## FRE7241 Algorithmic Portfolio Management Lecture#1, Fall 2024

Jerzy Pawlowski jp3900@nyu.edu

NYU Tandon School of Engineering

September 3, 2024

## Welcome Students!

My name is Jerzy Pawlowski jp3900@nyu.edu

I'm an adjunct professor at NYU Tandon because I love teaching and I want to share my professional knowledge with young, enthusiastic students.

I'm interested in applications of *machine learning* to *systematic investing*.

I'm an advocate of *open-source software*, and I share it on GitHub:

#### Mv GitHub account

In my finance career, I have worked as a hedge fund portfolio manager, CLO banker (structurer), and quant risk analyst.

Jerzy Pawlowski

Adjunct Professor at NYU Tandon School of Engineering
Greater New York City Area

Add profile section ▼ More...

Interested in applications of machine learning and high frequency data to systematic investing.

# FRE7241 Course Description and Objectives

## Course Description

The course will apply the R programming language to trend following, momentum trading, statistical arbitrage (pairs trading), and other active portfolio management strategies. The course will implement volatility and price forecasting models, asset pricing and factor models, and portfolio optimization. The course will apply machine learning techniques, such as parameter regularization (shrinkage), bagging and backtesting (cross-validation). This course is challenging, so it requires devoting a significant amount of time!

# FRE7241 Course Description and Objectives

## Course Description

The course will apply the R programming language to trend following, momentum trading, statistical arbitrage (pairs trading), and other active portfolio management strategies. The course will implement volatility and price forecasting models, asset pricing and factor models, and portfolio optimization. The course will apply machine learning techniques, such as parameter regularization (shrinkage), bagging and backtesting (cross-validation). This course is challenging, so it requires devoting a significant amount of time!

## Course Objectives

Students will learn through R coding exercises how to:

- download data from external sources, and to scrub and format it.
- estimate time series parameters, and fit models such as ARIMA, GARCH, and factor models.
- optimize portfolios under different constraints and risk-return objectives.
- backtest active portfolio management strategies and evaluate their performance.

## FRE7241 Course Description and Objectives

The course will implement volatility and price forecasting models, asset pricing and factor models, and portfolio optimization. The course will apply machine learning techniques, such as parameter regularization (shrinkage), bagging and backtesting (cross-validation). This course is challenging, so it requires devoting a significant amount of time!

## Course Objectives

Students will learn through R coding exercises how to:

- download data from external sources, and to scrub and format it.
- estimate time series parameters, and fit models such as ARIMA, GARCH, and factor models.
- optimize portfolios under different constraints and risk-return objectives.
- backtest active portfolio management strategies and evaluate their performance.

#### Course Recommendations

It's recommended that you take FRE6123 Financial Risk Management and Asset Pricing. The R language is considered to be challenging, so this course requires programming experience with other languages such as C++ or Python. Students with less programming experience are encouraged to first take FRE6871 R in Finance, and also FRE6883 Financial Computing by prof. Song Tang. Students should also have knowledge of basic statistics (random variables, estimators, hypothesis testing, regression, etc.)

## Homeworks and Tests

#### Homeworks and Tests

Grading will be based on homeworks and tests. There will be no final exam.

The tests will be announced several days in advance.

The homeworks and tests will require writing code, which should run directly when loaded into an R session, and should produce the required output, without any modifications.

The tests will be closely based on code contained in the lecture slides, so students are encouraged to become very familiar with those slides.

Students must submit their homework and test files only through Brightspace (not emails).

Students will be allowed to copy code from the lecture slides, and to copy from books or any online sources, but they will be required to provide references to those external sources (such as links or titles and page numbers).

Students are encouraged to use GitHub Copilot for RStudio.

Students will be required to bring their laptop computers to class and run the R Interpreter, and the RStudio Integrated Development Environment (*IDE*), during the lecture.

Homeworks will also include reading assignments designed to help prepare for tests.

Students are encouraged to use GitHub Copilot for RStudio.

Students will be required to bring their laptop computers to class and run the R Interpreter, and the RStudio Integrated Development Environment (*IDE*), during the lecture.

Homeworks will also include reading assignments designed to help prepare for tests.

#### Graduate Assistant

The graduate assistant (GA) will be Lakshay Dua ld3074@nyu.edu.

The GA will answer questions during office hours, or via *Brightspace* forums, not via emails. Please send emails regarding lecture matters from *Brightspace* (not personal emails).

## Tips for Solving Homeworks and Tests

## Tips for Solving Homeworks and Tests

The tests will require mostly copying code samples from the lecture slides, making some modifications to them, and combining them with other code samples.

Partial credit will be given even for code that doesn't produce the correct output, but that has elements of code that can be useful for producing the right answer.

So don't leave test assignments unanswered, and instead copy any code samples from the lecture slides that are related to the solution and make sense.

Contact the GA during office hours via text or phone, and submit questions to the GA or to me via Brightspace.

# Tips for Solving Homeworks and Tests

Partial credit will be given even for code that doesn't produce the correct output, but that has elements of code that can be useful for producing the right answer.

So don't leave test assignments unanswered, and instead copy any code samples from the lecture slides that are related to the solution and make sense.

Contact the GA during office hours via text or phone, and submit questions to the GA or to me via Brightspace.

#### Please Submit Minimal Working Examples With Your Questions

When submitting questions, please provide a *minimal working example* that produces the error in R, with the following items:

- $\bullet$  The  $complete\ \mathtt{R}$  code that produces the error, including the seed value for random numbers,
- The version of R (output of command: sessionInfo()), and the versions of R packages,
- The type and version of your operating system (Windows or OSX),
- The dataset file used by the R code,
- The text or screenshots of error messages,

You can read more about producing  $\it minimal\ working\ examples$  here: http://stackoverflow.com/help/mcve http://www.jaredknowles.com/journal/2013/5/27/writing-a-minimal-working-example-mwe-in-r

5/88

# **Course Grading Policies**

#### **Numerical Scores**

Homeworks and tests will be graded and assigned numerical scores. Each part of homeworks and tests will be graded separately and assigned a numerical score.

Maximum scores will be given only for complete code, that produces the correct output when it's pasted into an R session, without any modifications. As long as the R code uses the required functions and produces the correct output, it will be given full credit.

Partial credit will be given even for code that doesn't produce the correct output, but that has elements of code that can be useful for producing the right answer.

# **Course Grading Policies**

#### **Numerical Scores**

Homeworks and tests will be graded and assigned numerical scores. Each part of homeworks and tests will be graded separately and assigned a numerical score.

Maximum scores will be given only for complete code, that produces the correct output when it's pasted into an R session, without any modifications. As long as the R code uses the required functions and produces the correct output, it will be given full credit.

Partial credit will be given even for code that doesn't produce the correct output, but that has elements of code that can be useful for producing the right answer.

#### Letter Grades

Letter grades for the course will be derived from the percentage scores obtained for all the homeworks and tests. The percentage scores will be calculated by adding together the scores of all the homeworks and tests, and dividing them by the sum of the maximum scores. The percentage scores are usually very high - above 90%. So a very high percentage score will not guarantee an A letter grade, since grading will also depend on the difficulty of the assignments.

# **Course Grading Policies**

#### **Numerical Scores**

Homeworks and tests will be graded and assigned numerical scores. Each part of homeworks and tests will be graded separately and assigned a numerical score.

Maximum scores will be given only for complete code, that produces the correct output when it's pasted into an R session, without any modifications. As long as the R code uses the required functions and produces the correct output, it will be given full credit.

Partial credit will be given even for code that doesn't produce the correct output, but that has elements of code that can be useful for producing the right answer.

#### Letter Grades

Letter grades for the course will be derived from the percentage scores obtained for all the homeworks and tests. The percentage scores will be calculated by adding together the scores of all the homeworks and tests, and dividing them by the sum of the maximum scores. The percentage scores are usually very high - above 90%. So a very high percentage score will not guarantee an A letter grade, since grading will also depend on the difficulty of the assignments.

#### **Plagiarism**

Plagiarism (copying from other students) and cheating will be punished.

But copying code from lecture slides, books, or any online sources is allowed and encouraged.

Students must provide references to any external sources from which they copy code (such as links or titles and page numbers).

6/88

## FRE7241 Course Materials

## Lecture Slides

The course will be mostly self-contained, using detailed lecture slides containing extensive, working R code examples.

The course will also utilize data and tutorials which are freely available on the internet.

Jerzy Pawlowski (NYU Tandon)

## FRE7241 Course Materials

#### Lecture Slides

The course will be mostly self-contained, using detailed lecture slides containing extensive, working R code examples.

The course will also utilize data and tutorials which are freely available on the internet.

#### FRE7241 Recommended Textbooks

- Advances in Financial Machine Learning by Marcos Lopez de Prado Machine learning techniques
  applied to trading and portfolio management.
- Systematic Trading by Robert Carver Practical trading knowledge by an experienced portfolio manager.
- Systematic Investing by Robert Carver Practical investment knowledge by a successful investor.
- Quantitative Trading by Xin Guo, Tze Leung Lai, Howard Shek, Samuel Po-Shing Wong Advanced topics in quantitative trading by academic experts.
- Financial Data and Models Using R by Clifford Ang Good introduction to time series, portfolio
  optimization, and performance measures.
- Automated Trading by Chris Conlan How to implement practical computer trading systems.
- Statistics and Data Analysis for Financial Engineering by David Ruppert Introduces regression, cointegration, multivariate time series analysis, ARIMA, GARCH, CAPM, and factor models, with examples in R.
- Financial Risk Modelling and Portfolio Optimization with R by Bernhard Pfaff Introduces volatility models, portfolio optimization, and tactical asset allocation, with a great review of R packages and examples in R.

Many textbooks can be downloaded in electronic format from the NYU Library.

# FRE7241 Supplementary Books

- Introduction to Statistical Learning by Gareth James, Daniela Witten, Trevor Hastie, and Robert Tibshirani, introduces machine learning techniques using R, but without deep learning.
- Quantitative Risk Management by Alexander J. McNeil, Rudiger Frey, and Paul Embrechts: review of Value at Risk, factor models, ARMA and GARCH, extreme value theory, and credit risk models.
- Applied Econometrics with R by Christian Kleiber and Achim Zeileis, introduces advanced statistical models and econometrics.
- The Art of R Programming by Norman Matloff, contains a good introduction to R and to statistical models.
- Advanced R by Hadley Wickham, is the best book for learning the advanced features of R.
- Numerical Recipes in C++ by William Press, Saul Teukolsky, William Vetterling, and Brian Flannery, is a
  great reference for linear algebra and numerical methods, implemented in working C++ code.
- The books R in Action by Robert Kabacoff and R for Everyone by Jared Lander, are good introductions to R and to statistical models.
- Quant Finance books by Jerzy Pawlowski.
- Quant Trading books by Jerzy Pawlowski.

# FRE7241 Supplementary Materials

## Robert Carver's trading blog

Great blog about practical systematic trading and investments, with Python code:

http://qoppac.blogspot.com/

## Introduction to Computational Finance with R

Good course by prof. Eric Zivot, with lots of R examples:

https://www.datacamp.com/community/open-courses/computational-finance-and-financial-econometrics-with-r

Notepad++ is a free source code editor for MS Windows, that supports several programming languages, including R.

Notepad++ has a very convenient and fast search and replace function, that allows search and replace in multiple files.

http://notepad-plus-plus.org/

## The ETF Database

Exchange-traded Funds ( $\it{ETFs}$ ) are funds which invest in portfolios of assets, such as stocks, commodities, or bonds.

*ETFs* are shares in portfolios of assets, and they are traded just like stocks.

ETFs provide investors with convenient, low cost, and liquid instruments to invest in various portfolios of assets.

The file etf\_list.csv contains a database of exchange-traded funds (ETFs) and exchange traded notes (ETNs).

We will select a portfolio of *ETFs* for illustrating various investment strategies.

```
> # Select ETF symbols for asset allocation
> symbolv <- c("SPY", "VTI", "QQQ", "VEU", "EEM", "XLY", "XLP",
+ "XLE", "XLF", "XLV", "XLI", "XLB", "XLK", "XLU", "VYM", "IVW",
+ "IWB", "IWD", "IWF", "IEF", "TLT", "VNQ", "DBC", "GLD", "USO",
+ "VXX", "SVXY", "MTUM", "IVE", "VLUE", "QUAL", "VTV", "USMV", "AIE
> # Read etf database into data frame
> etflist <- read.csv(file="/Users/jerzy/Develop/lecture_slides/date
> rownames(etflist) <- etflist$Symbol
> # Select from etflist only those ETF's in symbolv
> etflist <- etflist[symbolv, ]
> # Shorten names
> etfnames <- sapply(etflist$Name, function(name) {
    namesplit <- strsplit(name, split=" ")[[1]]
    namesplit <- namesplit[c(-1, -NROW(namesplit))]
    name_match <- match("Select", namesplit)
   if (!is.na(name_match))
      namesplit <- namesplit[-name_match]
    paste(namesplit, collapse=" ")
+ }) # end sapply
> etflist$Name <- etfnames
> etflist["IEF", "Name"] <- "10 year Treasury Bond Fund"
> etflist["TLT", "Name"] <- "20 plus year Treasury Bond Fund"
> etflist["XLY", "Name"] <- "Consumer Discr. Sector Fund"
> etflist["EEM", "Name"] <- "Emerging Market Stock Fund"
> etflist["MTUM", "Name"] <- "Momentum Factor Fund"
> etflist["SVXY", "Name"] <- "Short VIX Futures"
> etflist["VXX", "Name"] <- "Long VIX Futures"
> etflist["DBC", "Name"] <- "Commodity Futures Fund"
> etflist["USO", "Name"] <- "WTI Oil Futures Fund"
> etflist["GLD", "Name"] <- "Physical Gold Fund"
```

## ETF Database for Investment Strategies

The database contains *ETFs* representing different industry sectors and investment styles.

The ETFs with names  $X^*$  represent industry sector funds (energy, financial, etc.)

The ETFs with names  $I^*$  represent style funds (value, growth, size).

IWB is the Russell 1000 small-cap fund.

The SPY ETF owns the S&P500 index constituents. SPY is the biggest, the most liquid, and the oldest ETF. SPY has over \$400 billion of shares outstanding, and trades over \$20 billion per day, at a bid-ask spread of only one tick (cent=\$0.01, or about 0.0022%).

The *QQQ ETF* owns the *Nasdaq-100* index constituents.

MTUM is an ETF which owns a stock portfolio representing the momentum factor.

DBC is an ETF providing the total return on a portfolio of commodity futures.

Symbol	Name	Fund. Type
SPY	S&P 500	US Equity ETF
VTI	Total Stock Market	US Equity ETF
QQQ	QQQ Trust	US Equity ETF
VEU	FTSE All World Ex US	Global Equity ETF
EEM	Emerging Market Stock Fund	Global Equity ETF
XLY	Consumer Discr. Sector Fund	US Equity ETF
XLP	Consumer Staples Sector Fund	US Equity ETF
XLE	Energy Sector Fund	US Equity ETF
XLF	Financial Sector Fund	US Equity ETF
XLV	Health Care Sector Fund	US Equity ETF
XLI	Industrial Sector Fund	US Equity ETF
XLB	Materials Sector Fund	US Equity ETF
XLK	Technology Sector Fund	US Equity ETF
XLU	Utilities Sector Fund	US Equity ETF
VYM	Large-cap Value	US Equity ETF
IVW	S&P 500 Growth Index Fund	US Equity ETF
IWB	Russell 1000	US Equity ETF
IWD	Russell 1000 Value	US Equity ETF
IWF	Russell 1000 Growth	US Equity ETF
IEF	10 year Treasury Bond Fund	US Fixed Income ETF
TLT	20 plus year Treasury Bond Fund	US Fixed Income ETF
VNQ	REIT ETF - DNQ	US Equity ETF
DBC	Commodity Futures Fund	Commodity Based ETI
GLD	Physical Gold Fund	Commodity Based ETI
USO	WTI Oil Futures Fund	Commodity Based ETI
VXX	Long VIX Futures	Commodity Based ETI
SVXY	Short VIX Futures	Commodity Based ETI
MTUM	Momentum Factor Fund	US Equity ETF
IVE	S&P 500 Value Index Fund	US Equity ETF
VLUE	MSCI USA Value Factor	US Equity ETF
QUAL	MSCI USA Quality Factor	US Equity ETF
VTV	Value	US Equity ETF
USMV	MSCI USA Minimum Volatility Fund	US Equity ETF
AIEQ	Al Powered Equity	US Asset Allocation E

# Exchange Traded Notes (ETNs)

ETNs are similar to ETFs, with the difference that ETFs are shares in a fund which owns the underlying assets, while ETNs are notes from issuers which promise payouts according to a formula tied to the underlying asset.

ETFs are similar to mutual funds, while ETNs are similar to corporate bonds.

ETNs are technically unsecured corporate debt, but instead of fixed coupons, they promise to provide returns on a market index or futures contract.

The  $\ensuremath{\textit{ETN}}$  issuer promises the payout and is responsible for tracking the index.

The ETN investor has counterparty credit risk to the ETN issuer.

VXX is an ETN providing the total return of  $long\ VIX$  futures contracts (specifically the  $S\&P\ VIX\ Short$ -Term Futures Index).

VXX is bearish because it's long VIX futures, and the VIX rises when stock prices drop.

SVXY is an ETF providing the total return of short VIX futures contracts.

SVXY is bullish because it's short VIX futures, and the VIX drops when stock prices rise.

# Downloading ETF Prices Using Package quantmod

The function getSymbols() downloads time series data into the specified *environment*.

getSymbols() downloads the daily *OHLC* prices and trading volume (Open, High, Low, Close, Adjusted, Volume).

getSymbols() creates objects in the specified environment from the input strings (names), and assigns the data to those objects, without returning them as a function value. as a side effect.

If the argument "auto.assign" is set to FALSE, then getSymbols() returns the data, instead of assigning it silently.

Yahoo data quality deteriorated significantly in 2017, and Google data quality is also poor, leaving Tiingo and Alpha Vantage as the only major providers of free daily OHLC stock prices.

But Quandl doesn't provide free *ETF* prices, leaving *Alpha Vantage* as the best provider of free daily *ETF* prices.

```
> # Select ETF symbols for asset allocation
> symboly <- c("SPY", "VTI", "QQQ", "VEU", "EEM", "XLY", "XLP",
+ "XLE", "XLF", "XLV", "XLI", "XLB", "XLK", "XLU", "VYM", "IVW",
+ "IWB", "IWD", "IWF", "IEF", "TLT", "VNQ", "DBC", "GLD", "USO",
+ "VXX", "SVXY", "MTUM", "IVE", "VLUE", "QUAL", "VTV", "USMV", "AIE
> library(rutils) # Load package rutils
> etfenv <- new.env() # New environment for data
> # Boolean vector of symbols already downloaded
> isdown <- symboly %in% ls(etfeny)
> # Download data for symbolv using single command - creates pacing
> getSymbols.av(symboly, adjust=TRUE, env=etfeny,
   output.size="full", api.key="T7JPW54ES8G75310")
> # Download data from Alpha Vantage using while loop
> nattempts <- 0 # number of download attempts
> while ((sum(!isdown) > 0) & (nattempts < 10)) {
    # Download data and copy it into environment
   nattempts <- nattempts + 1
   cat("Download attempt = ", nattempts, "\n")
   for (symboln in na.omit(symbolv[!isdown][1:5])) {
     cat("Processing: ", symboln, "\n")
      tryCatch( # With error handler
+ quantmod::getSymbols.av(symboln, adjust=TRUE, env=etfenv, auto.as
+ # Error handler captures error condition
+ error=function(msg) {
   print(paste0("Error handler: ", msg))
+ }, # end error handler
+ finally=print(paste0("Symbol = ", symboln))
      ) # end tryCatch
```

# Update vector of symbols already downloaded isdown <- symbolv %in% ls(etfenv) cat("Pausing 1 minute to avoid pacing...\n")

> # Download all symbolv using single command - creates pacing erro > # quantmod::getSymbols.av(symbolv, env=etfenv, adjust=TRUE, from=

} # end for

+ Sys.sleep(65) + } # end while

# Inspecting ETF Prices in an Environment

The function get() retrieves objects that are referenced using character strings, instead of their names.

The function eapply() is similar to lapply(), and applies a function to objects in an *environment*, and returns a list.

```
> ls(etfenv) # List files in etfenv
> # Get class of object in etfenv
> class(get(x=symbolv[1], envir=etfenv))
> # Another way
> class(etfenv$VTI)
> colnames(etfenv$VTI)
> # Get first 3 rows of data
> head(etfenv$VTI, 3)
> # Get last 11 rows of data
> tail(etfenv$VTI, 11)
> # Get class of all objects in etfenv
> eapply(etfeny, class)
> # Get class of all objects in R workspace
> lapply(ls(), function(namev) class(get(namev)))
> # Get end dates of all objects in etfenv
> as.Date(sapply(etfenv, end))
```

# Adjusting Stock Prices Using Package quantmod

Traded stock and bond prices experience jumps after splits and dividends, and must be adjusted to account for them.

The function  ${\tt adjustOHLC}()$  adjusts  ${\it OHLC}$  prices.

The function get() retrieves objects that are referenced using character strings, instead of their names.

The function assign() assigns a value to an object in a specified *environment*, by referencing it using a character string (name).

The functions get() and assign() allow retrieving and assigning values to objects that are referenced using character strings.

The function mget() accepts a vector of strings and returns a list of the corresponding objects extracted from an *environment*.

If the argument "adjust" in function getSymbols() is set to TRUE, then getSymbols() returns adjusted data.

+ } # end for

## **Extracting Time Series from Environments**

The function mget() accepts a vector of strings and returns a list of the corresponding objects extracted from an *environment*.

The extractor (accessor) functions from package quantmod: C1(), Vo(), etc., extract columns from OHLC data.

A list of *xts* series can be flattened into a single *xts* series using the function do.call().

The function do.call() executes a function call using a function name and a list of arguments.

do.call() passes the list elements individually, instead of passing the whole list as one argument.

The function eapply() is similar to lapply(), and applies a function to objects in an *environment*, and returns a list.

Time series can also be extracted from an *environment* by coercing it into a list, and then subsetting and merging it into an *xts* series using the function do.call().

```
> library(rutils) # Load package rutils
> # Define ETF symbols
> symbolv <- c("VTI", "VEU", "IEF", "VNQ")
> # Extract symbolv from rutils::etfenv
> pricev <- mget(symbolv, envir=rutils::etfenv)
> # pricev is a list of xts series
> class(pricev)
> class(pricev[[1]])
> tail(pricev[[1]])
> # Extract close prices
> pricev <- lapply(pricev, quantmod::C1)
> # Collapse list into time series the hard way
> prices2 <- cbind(pricev[[1]], pricev[[2]], pricev[[3]], pricev[[4
> class(price2)
> dim(price2)
> # Collapse list into time series using do.call()
> pricev <- do.call(cbind, pricev)
> all.equal(price2, pricey)
> class(pricev)
> dim(pricev)
> # Or extract and cbind in single step
> pricev <- do.call(cbind, lapply(
    mget(symboly, envir=rutils::etfeny), quantmod::Cl))
> # Or extract and bind all data, subset by symboly
> pricev <- lapply(symbolv, function(symboln) {
      quantmod::Cl(get(symboln, envir=rutils::etfenv))
+ }) # end lapply
> # Or loop over etfenv without anonymous function
> pricev <- do.call(cbind,
    lapply(as.list(rutils::etfenv)[symbolv], quantmod::C1))
> # Same, but works only for OHLC series - produces error
> pricev <- do.call(cbind,
    eapply(rutils::etfenv, quantmod::Cl)[symbolv])
```

# Managing Time Series

Time series columns can be renamed, and then saved into .csv files.  $\label{eq:csv}$ 

The function strsplit() splits the elements of a character vector.

The package zoo contains functions write.zoo() and read.zoo() for writing and reading zoo time series from .txt and .csv files.

The function eapply() is similar to lapply(), and applies a function to objects in an *environment*, and returns a list.

The function assign() assigns a value to an object in a specified *environment*, by referencing it using a character string (name).

The function save() writes objects to compressed binary .RData files.

```
> # Column names end with " Close"
> colnames(pricev)
> strsplit(colnames(pricev), split="[.]")
> do.call(rbind, strsplit(colnames(pricev), split="[.]"))
> do.call(rbind, strsplit(colnames(pricev), split="[.]"))[, 1]
> # Drop ".Close" from colnames
> colnames(pricev) <- rutils::get_name(colnames(pricev))
> # Nr
> # colnames(pricev) <- do.call(rbind,
> # strsplit(colnames(pricev), split="[.]"))[, 1]
> tail(pricev, 3)
> # Which objects in global environment are class xts?
> unlist(eapply(globalenv(), is.xts))
> # Save xts to csv file
> write.zoo(pricev,
+ file="/Users/jerzy/Develop/lecture_slides/data/etf_series.csv"
> # Copy prices into etfenv
> etfenv$prices <- pricev
> # Nr
> assign("pricev", pricev, envir=etfenv)
> # Save to .RData file
```

> save(etfenv, file="etf data,RData")

# Calculating Percentage Returns from Close Prices

The function quantmod::dailyReturn() calculates the percentage daily returns from the *Close* prices.

The lapply() and sapply() functionals perform a loop over the columns of *zoo* and *xts* series.

```
> # Extract VTI prices
> pricev <- etfenv$prices[ ,"VTI"]
> pricev <- na.omit(pricev)
> # Calculate percentage returns "by hand"
> pricel <- as.numeric(pricev)
> pricel <- c(pricel[1], pricel[-NROW(pricel)])
> pricel <- xts(pricel, zoo::index(pricev))
> retp <- (pricev-pricel)/pricel
> # Calculate percentage returns using dailyReturn()
> retd <- quantmod::dailyReturn(pricev)
> head(cbind(retd, retp))
> all.equal(retd, retp, check.attributes=FALSE)
> # Calculate returns for all prices in etfenv$prices
> retp <- lapply(etfenv$prices, function(xtsv) {
    retd <- quantmod::dailyReturn(na.omit(xtsv))
    colnames(retd) <- names(xtsv)
    retd
+ }) # end lapply
> # "retp" is a list of xts
> class(retp)
> class(retp[[1]])
> # Flatten list of xts into a single xts
> retp <- do.call(cbind, retp)
> class(retp)
> dim(retp)
> # Copy retp into etfenv and save to .RData file
> # assign("retp", retp, envir=etfenv)
> etfenv$retp <- retp
> save(etfenv, file="/Users/jerzy/Develop/lecture_slides/data/etf_d
```

# Managing Data Inside Environments

The function as.environment() coerces objects (listv) into an environment.

The function eapply() is similar to lapply(), and applies a function to objects in an *environment*, and returns a list.

The function mget() accepts a vector of strings and returns a list of the corresponding objects extracted from an *environment*.

```
> library(rutils)
> startd <- "2012-05-10": endd <- "2013-11-20"
> # Select all objects in environment and return as environment
> newenv <- as.environment(eapply(etfenv, "[",

           })), envir=newenv)
```

# Stock Databases And Survivorship Bias

The file sp500\_constituents.csv contains a data frame of over 700 present (and also some past) S&P500 index constituents.

The file sp500\_constituents.csv is updated with stocks recently added to the S&P500 index by downloading the SPY ETF Holdings.

But the file sp500\_constituents.csv doesn't include companies that have gone bankrupt. For example, it doesn't include Enron, which was in the S&P500 index before it went bankrupt in 2001.

Most databases of stock prices don't include companies that have gone bankrupt or have been liquidated.

This introduces a survivorship bias to the data, which can skew portfolio simulations and strategy backtests.

Accurate strategy simulations require starting with a portfolio of companies at a "point in time" in the past, and tracking them over time.

Research databases like the WRDS database provide stock prices of companies that are no longer traded.

The stock tickers are stored in the column "Ticker" of the sp500 data frame.

Some tickers (like "BRK.B" and "BF.B") are not valid symbols in Tiingo, so they must be renamed.

- > # Load data frame of S&P500 constituents from CSV file > sp500 <- read.csv(file="/Users/jerzy/Develop/lecture\_slides/data/
- > # Inspect data frame of S&P500 constituents > dim(sp500)
- > colnames(sp500)
- > # Extract tickers from the column Ticker
- > symbolv <- sp500\$Ticker > # Get duplicate tickers
- > tablev <- table(symbolv)
- > duplicatv <- tablev[tablev > 1]
- > duplicatv <- names(duplicatv)
- > # Get duplicate records (rows) of sp500 > sp500[symbolv %in% duplicatv, ]
- > # Get unique tickers
- > symbolv <- unique(symbolv)
- > # Find index of ticker "BRK.B"
- > which(symbolv=="BRK.B") > # Rename "BRK.B" to "BRK-B" and "BF.B" to "BF-B"
- > symbolv[which(symbolv=="BRK.B")] <- "BRK-B"
- > symbolv[which(symbolv=="BF.B")] <- "BF-B"

# Downloading Stock Time Series From Tiingo

Yahoo data quality deteriorated significantly in 2017, and Google data quality is also poor, leaving Tiingo, Alpha Vantage, and Quandl as the only major providers of free daily OHLC stock prices.

But Quandl doesn't provide free *ETF* prices, while *Tiingo* does.

The function getSymbols() has a *method* for downloading time series data from *Tiingo*, called getSymbols.tiingo().

Users must first obtain a *Tiingo API key*, and then pass it in getSymbols.tiingo() calls:

https://www.tiingo.com/

Note that the data are downloaded as xts time series, with a date-time index of class POSIXct (not Date).

```
> # Load package rutils
> library(rutils)
> # Create new environment for data
> sp500env <- new.env()
> # Boolean vector of symbols already downloaded
> isdown <- symbolv %in% ls(sp500env)
> # Download in while loop from Tiingo and copy into environment
> nattempts <- 0 # Number of download attempts
> while ((sum(!isdown) > 0) & (nattempts<3)) {
   # Download data and copy it into environment
   nattempts <- nattempts + 1
   cat("Download attempt = ", nattempts, "\n")
   for (symboln in symbolv[!isdown]) {
     cat("processing: ", symboln, "\n")
     tryCatch( # With error handler
+ quantmod::getSymbols(symboln, src="tiingo", adjust=TRUE, auto.ass
             from="1990-01-01", env=sp500env, api.key="j84ac2b9c5bd
+ # Error handler captures error condition
+ error=function(msg) {
   print(paste0("Error handler: ", msg))
+ }. # end error handler
+ finally=print(paste0("Symbol = ", symboln))
      ) # end trvCatch
   } # end for
   # Update vector of symbols already downloaded
   isdown <- symbolv %in% ls(sp500env)
   Sys.sleep(2) # Wait 2 seconds until next attempt
+ } # end while
> class(sp500env$AAPL)
> class(zoo::index(sp500env$AAPL))
> tail(sp500env$AAPL)
> symboly[!isdown]
```

# Coercing Date-time Indices

The date-time indices of the *OHLC* stock prices are in the POSIXct format suitable for intraday prices, not daily prices.

The function as.Date() coerces POSIXct objects into Date objects.

The function get() retrieves objects that are referenced using character strings, instead of their names.

The function assign() assigns a value to an object in a specified *environment*, by referencing it using a character string (name).

The functions get() and assign() allow retrieving and assigning values to objects that are referenced using character strings.

- > # The date-time index of AAPL is POSIXct
- > class(zoo::index(sp500env\$AAPL))
- > # Coerce the date-time index of AAPL to Date
- > zoo::index(sp500env\$AAPL) <- as.Date(zoo::index(sp500env\$AAPL))
  > # Coerce all the date-time indices to Date
- > for (symboln in ls(sp500env)) {
- ohlc <- get(symboln, envir=sp500env)
- + zoo::index(ohlc) <- as.Date(zoo::index(ohlc))
- + zoo::index(onic) <- as.Date(zoo::index(onic))
  + assign(symboln, ohlc, envir=sp500env)
- + } # end for

LOWES OHLC Stock Prices

# Managing Exceptions in Stock Symbols

The column names for symbol "LOW" (Lowe's company) must be renamed for the extractor function quantmod::Lo() to work properly.

Tickers which contain a dot in their name (like "BRK.B") are not valid symbols in R, so they must be downloaded separately and renamed.

```
> # "LOW.Low" is a bad column name
> colnames(sp500env$LOW)
> strsplit(colnames(sp500env$LOW), split="[.]")
> do.call(cbind, strsplit(colnames(sp500env$LOW), split="[.]"))
> do.call(cbind, strsplit(colnames(sp500env$LOW), split="[.]"))[2,
> # Extract proper names from column names
> namev <- rutils::get_name(colnames(sp500env$LOW), field=2)
> # namev <- do.call(rbind, strsplit(colnames(sp500env$LOW),
                                      split="[.]"))[, 2]
> # Rename "LOW" colnames to "LOWES"
> colnames(sp500env$LOW) <- paste("LOVES", namev, sep=".")
> sp500env$LOWES <- sp500env$LOW
> rm(LOW, envir=sp500env)
> # Rename BF-B colnames to "BFB"
```

> colnames(sp500env\$"BF-B") <- paste("BFB", namev, sep=".") > sp500env\$BFB <- sp500env\$"BF-B" > # Plot OHLC candlestick chart for LOWES > rm("BF-B", envir=sp500env) > chart Series(x=sp500env\$LOWES["2019-12/"]. > # Rename BRK-B colnames TA="add\_Vo()", name="LOWES OHLC Stock Prices") > sp500env\$BRKB <- sp500env\$'BRK-B' > # Plot dygraph > rm('BRK-B', envir=sp500env) > colnames(sp500env\$BRKB) <- gsub("BRK-B", "BRKB", colnames(sp500en + dvCandlestick() > # Save OHLC prices to .RData file > save(sp500env, file="/Users/jerzy/Develop/lecture slides/data/sp500.RData")

> # Download "BRK.B" separately with auto.assign=FALSE

> # colnames(BRKB) <- paste("BRKB", namev, sep=".")

## S&P500 Stock Index Constituent Prices

The file sp500.RData contains the environment sp500\_env with OHLC prices and trading volumes of S&P500 stock index constituents.

The S&P500 stock index constituent data is of poor quality before 2000, so we'll mostly use the data after the year 2000.

```
> # Load S&P500 constituent stock prices
> load("/Users/jerzy/Develop/lecture slides/data/sp500.RData")
> pricev <- eapply(sp500env, quantmod::C1)
> pricev <- rutils::do_call(cbind, pricev)
> # Carry forward non-NA prices
> pricev <- zoo::na.locf(pricev, na.rm=FALSE)
> # Drop ".Close" from column names
> colnames(pricev)
> colnames(pricev) <- rutils::get_name(colnames(pricev))
> # Nr
> # colnames(pricev) <- do.call(rbind,
   strsplit(colnames(pricev), split="[.]"))[, 1]
```

- > # Calculate percentage returns of the S&P500 constituent stocks
- > # retp <- xts::diff.xts(log(pricev))
- > retp <- xts::diff.xts(pricev)/
- rutils::lagit(pricev, pad\_zeros=FALSE)
- > set.seed(1121, "Mersenne-Twister", sample.kind="Rejection")
- > samplev <- sample(NCOL(retp), s=100, replace=FALSE)
- > prices100 <- pricev[, samplev] > returns100 <- retp[, samplev]
- > save(pricev, prices100,
- file="/Users/jerzy/Develop/lecture\_slides/data/sp500\_prices.RData")
- > save(retp, returns100,
- file="/Users/jerzy/Develop/lecture slides/data/sp500 returns.RData")

Number of S&P500 Constituents Without Prices

- > datav <- rowSums(is.na(pricev)) > datav <- xts::xts(datav, order.by=zoo::index(pricev))
- > dvgraphs::dvgraph(datav, main="Number of S&P500 Constituents With
- + dvOptions(colors="blue", strokeWidth=2)

## S&P500 Stock Portfolio Index

The price-weighted index of S&P500 constituents closely follows the VTI ETF.

```
> # Calculate price weighted index of constituent
> ncols <- NCOL(pricev)
> pricev <- zoo::na.locf(pricev, fromLast=TRUE)
> indeks <- xts(rouSums(pricev)/ncols, zoo::index(pricev))
> colnames(indeks) <- "index"
> # Combine index with VII
> datav <- cbind(indeks[zoo::index(etfenv$VII)], etfenv$VII[, 4])
> colnames <- c("index", "VII")
> colnames (datav) <- colnamev
> # Plot index with VII
> endd <- rutils::calc_endpoints(datav, interval="weeks")
> dygraphs::dygraph(log(datav)[endd],
+ main="S&P 500 Price-weighted Index and VII") %>%
+ dyAxis("y", label=colnamev[1], independentTicks=TRUE) %>%
+ dyAxis("y", label=colnamev[2], independentTicks=TRUE) %>%
```

dySeries(name=colnamev[1], axis="y", col="red") %>%

dySeries(name=colnamev[2], axis="y2", col="blue")

+ symboln + }) # end lapply

> unlist(filens)

## Writing Time Series To Files

The data from Tiingo is downloaded as xts time series, with a date-time index of class POSIXct (not Date).

The function save() writes objects to compressed binary .RData files.

The easiest way to share data between R and Excel is through .csv files.

The package zoo contains functions write.zoo() and

read.zoo() for writing and reading zoo time series from .txt and .csv files.

The function data.table::fread() reads from .csv files over 6 times faster than the function read.csv()!

The function data.table::fwrite() writes to .csv files over 12 times faster than the function write.csv(), and 278 times faster than function cat()!

> # Or using eapply() and data.table::fwrite()

> filens <- eapply(sp500env , function(xtsv) {

filen <- rutils::get\_name(colnames(xtsv)[1])

+ } # end for

> # Or using fread()
> for (filen in filens) {

# end for

xtsv <- data.table::fread(filen)

assign(symboln, xtsv, envir=sp500env)

xtsv <- xts::xts(xtsv[, -1], as.Date(xtsv[, 1]))
symboln <- rutils::get\_name(colnames(xtsv)[1])</pre>

data.table::setDF(xtsv)

## Reading Time Series from Files

The function Sys.glob() listv files matching names obtained from wildcard expansion.

The easiest way to share data between R and Excel is through .csv files.

The function as.Date() parses character strings, and coerces numeric and POSIXct objects into Date objects.

The function data.table::setDF() coerces a data table object into a data frame using a side effect, without making copies of data.

The function data.table::fread() reads from .csv files over 6 times faster than the function read.csv()!

> # Remove all files from environment(if necessary)

# Downloading Stock Time Series From Alpha Vantage

Yahoo data quality deteriorated significantly in 2017, and Google data quality is also poor, leaving Tiingo, Alpha Vantage, and Quandl as the only major providers of free daily OHLC stock prices.

But Quandl doesn't provide free *ETF* prices, while *Alpha Vantage* does.

The function getSymbols() has a method for downloading time series data from Alpha Vantage, called getSymbols.av().

Users must first obtain an Alpha Vantage API key, and then pass it in getSymbols.av() calls: https://www.alphavantage.co/

The function adjustOHLC() with argument use.Adjusted=TRUE, adjusts all the OHLC price columns, using the Adjusted price column.

```
> rm(list=ls(sp500env), envir=sp500env)
> # Download in while loop from Alpha Vantage and copy into environ
> isdown <- symbolv %in% ls(sp500env)
> nattempts <- 0
> while ((sum(!isdown) > 0) & (nattempts < 10)) {
    # Download data and copy it into environment
   nattempts <- nattempts + 1
   for (symboln in symbolv[!isdown]) {
     cat("processing: ", symboln, "\n")
     tryCatch( # With error handler
+ quantmod::getSymbols(symboln, src="av", adjust=TRUE, auto.assign=
             output.size="full", api.key="T7JPW54ES8G75310"),
+ # error handler captures error condition
+ error=function(msg) {
   print(paste0("Error handler: ", msg))
+ }. # end error handler
+ finally=print(paste0("Symbol = ", symboln))
      ) # end tryCatch
    } # end for
   # Update vector of symbols already downloaded
   isdown <- symbolv %in% ls(sp500env)
   Sys.sleep(2) # Wait 2 seconds until next attempt
+ } # end while
> # Adjust all OHLC prices in environment
> for (symboln in ls(sp500env)) {
   assign(symboln.
     adjustOHLC(get(x=symboln, envir=sp500env), use.Adjusted=TRUE)
     envir=sp500env)
+ } # end for
```

## Downloading The S&P500 Index Time Series From Yahoo

The S&P500 stock market index is a capitalization-weighted average of the 500 largest U.S. companies, and covers about 80% of the U.S. stock market capitalization.

Notice: Yahoo no longer provides a public API for data.

There are workarounds but they're tedious.

Yahoo provides daily OHLC prices for the S&P500 index (symbol  $^{\circ}GSPC$ ), and for the S&P500 total return index (symbol ^SP500TR).

But special characters in some stock symbols, like "-" or "^" are not allowed in R names.

For example, the symbol  $^{\circ}GSPC$  for the S&P500 stock market index isn't a valid name in R.

The function setSymbolLookup() creates valid names corresponding to stock symbols, which are then used by the function getSymbols() to create objects with the valid names

Yahoo data quality deteriorated significantly in 2017. and Google data quality is also poor, leaving Alpha Vantage and Quandl as the only major providers of free daily OHLC stock prices.

```
> # Assign name SP500 to ^GSPC symbol
> quantmod::setSymbolLookup(SP500=list(name="^GSPC", src="yahoo"))
> quantmod::getSymbolLookup()
> # View and clear options
> options("getSymbols.sources")
> options(getSymbols.sources=NULL)
> # Download S&P500 prices into etfenv
> quantmod::getSymbols("SP500", env=etfenv,
      adjust=TRUE, auto.assign=TRUE, from="1990-01-01")
> chart_Series(x=etfenv$SP500["2016/"],
```

TA="add\_Vo()", name="S&P500 index")

# Downloading The DJIA Index Time Series From Yahoo

The Dow Jones Industrial Average (*DJIA*) stock market index is a price-weighted average of the 30 largest U.S. companies (same number of shares per company).

Yahoo provides daily OHLC prices for the DJIA index (symbol ^DJI), and for the DJITR total return index (symbol DJITR).

But special characters in some stock symbols, like "-" or "^" are not allowed in R names.

For example, the symbol *DJI* for the *DJIA* stock market index isn't a valid name in R.

The function setSymbolLookup() creates valid names corresponding to stock symbols, which are then used by the function getSymbols() to create objects with the valid names.

```
> # Assign name DJIA to 'DJI symbol
> setSymbolLookup(DJIA=list(name="'DJI", src="yahoo"))
> getSymbolLookup()
> # view and clear options
> options('getSymbols.sources")
> options(getSymbols.sources=NULL)
> # Download DJIA prices into etfenv
> quantmod: getSymbols('DJIA'", env=etfenv,
+ adjust=TRUE, auto.assign=TRUE, from="1990-01-01")
> chart_Series(x=etfenv$DJIA["'2016/"],
```

TA="add\_Vo()", name="DJIA index")

# Calculating Prices and Returns From OHLC Data

The function na.locf() from package zoo replaces NA values with the most recent non-NA values prior to it.

The function na.locf() with argument fromLast=TRUE replaces NA values with non-NA values in reverse order, starting from the end.

The function rutils::get\_name() extracts symbol names (tickers) from a vector of character strings.

```
> pricev <- eapply(sp500env, quantmod::Cl)
> pricev <- rutils::do_call(cbind, pricev)
> # Carry forward non-NA prices
> pricev <- zoo::na.locf(pricev, na.rm=FALSE)
> # Get first column name
> colnames(pricev[, 1])
> rutils::get_name(colnames(pricev[, 1]))
> # Modify column names
> colnames(pricey) <- rutils::get name(colnames(pricey))
> # colnames(pricev) <- do.call(rbind.
> # strsplit(colnames(pricev), split="[.]"))[, 1]
> # Calculate percentage returns
> retp <- xts::diff.xts(pricev)/
+ rutils::lagit(pricev, pad_zeros=FALSE)
> # Select a random sample of 100 prices and returns
> set.seed(1121, "Mersenne-Twister", sample.kind="Rejection")
> samplev <- sample(NCOL(retp), s=100, replace=FALSE)
> prices100 <- pricev[, samplev]
> returns100 <- retp[, samplev]
> # Save the data into binary files
> save(pricev, prices100,
       file="/Users/jerzy/Develop/lecture slides/data/sp500 prices
> save(retp, returns100,
       file="/Users/jerzy/Develop/lecture_slides/data/sp500_returns
```

# Downloading Stock Prices From Polygon

Polygon is a premium provider of live and historical stock price data, both daily and intraday (minutes).

Polygon provides 2 years of daily historical stock prices for free. But users must first obtain a Polygon API key. Polygon provides the historical OHLC stock prices in

JSON format.

JSON (JavaScript Object Notation) is a data format consisting of symbol-value pairs.

The package *jsonlite* contains functions for managing data in *JSON* format.

The functions fromJSON() and toJSON() convert data from JSON format to R objects, and vice versa.

The functions read\_json() and write\_json() read and write JSON format data in files.

The function download.file() downloads data from an internet website URL and writes it to a file.

```
> # Setup code
> symboln <- "SPY"
> startd <- as.Date("1990-01-01")</pre>
> todayd <- Sys.Date()
> tspan <- "day"
> # Replace below your own Polygon API key
> apikey <- "SEpnsBpiRyONMJd148r6d0o0_pjmCu5r"
> # Create url for download
> urll <- paste0("https://api.polygon.io/v2/aggs/ticker/", symboln,
> # Download SPY OHLC prices in JSON format from Polygon
> ohlc <- jsonlite::read_json(urll)
> class(ohlc)
> NROW(ohlc)
> names(ohlc)
> # Extract list of prices from json object
> ohlc <- ohlc$results
> # Coerce from list to matrix
> ohlc <- lapply(ohlc, unlist)
> ohlc <- do.call(rbind, ohlc)
> # Coerce time from milliseconds to dates
> datev <- ohlc[, "t"]/1e3
> datev <- as.POSIXct(datev, origin="1970-01-01")
> datev <- as.Date(datev)
> tail(datev)
> # Coerce from matrix to xts
> ohlc <- ohlc[, c("o","h","l","c","v","vw")]
> colnames(ohlc) <- c("Open", "High", "Low", "Close", "Volume", "VW
> ohlc <- xts::xts(ohlc, order.bv=datev)
> tail(ohlc)
> # Save the xts time series to compressed RData file
> save(ohlc, file="/Users/jerzy/Data/spy_daily.RData")
> # Candlestick plot of SPY OHLC prices
> dygraphs::dygraph(ohlc[, 1:4], main=paste("Candlestick Plot of",
+ dygraphs::dyCandlestick()
```

# Downloading Multiple Stock Prices From Polygon

The stock prices for multiple stocks can be downloaded in a while() loop.

```
> # Select ETF symbols for asset allocation
> symbolv <- c("SPY", "VTI", "QQQ", "VEU", "EEM", "XL
+ "XLE", "XLF", "XLI", "XLE", "XLE", "YLE", "YLU", "V
+ "TVB", "TWP", "TYF", "TEF", "TTT", "VNQ", "DBC", "G
+ "VXX", "MTUM", "IVE", "VLUE", "QUAL", "VTV"
> # Setup code
> etfenv <- new.env() # New environment for data
> # Boolean vector of symbols already downloaded
> isdown <- symbolv %in% ls(etfenv)
```

```
> # Download data from Polygon using while loop
> while (sum(!isdown) > 0) {
   for (symboln in symbolv[!isdown]) {
      cat("Processing:", symboln, "\n")
      tryCatch({ # With error handler
+ # Download OHLC bars from Polygon into JSON format file
+ urll <- paste0("https://api.polygon.io/v2/aggs/ticker/", symboln, "/range/1/"

# Calculating the Stock Alphas, Betas, and Other Performance Statistics

The package *PerformanceAnalytics* contains functions for calculating risk and performance statistics, such as the *variance*, *skewness*, *kurtosis*, *beta*, *alpha*, etc.

The function PerformanceAnalytics::table.CAPM() calculates the beta  $\beta$  and alpha  $\alpha$  values, the Treynor ratio, and other performance statistics.

The function PerformanceAnalytics::table.Stats() calculates a data frame of risk and return statistics of the return distributions.

```
> prices <- eapply(etfenv, quantmod::Cl)
> prices <- do.call(cbind, prices)
> # Drop ".Close" from colnames
> colnames(prices) <- do.call(rbind, strsplit(colnames(prices), spl
> # Calculate the log returns
> retp <- xts::diff.xts(log(prices))
> # Copy prices and returns into etfenv
> etfenv$prices <- prices
> etfenv$retp <- retp
> # Copy symbolv into etfenv
> etfenv$symbolv <- symbolv
> # Calculate the risk-return statistics
> riskstats <- PerformanceAnalytics::table.Stats(retp)
> # Transpose the data frame
> riskstats <- as.data.frame(t(riskstats))
> # Add Name column
> riskstats$Name <- rownames(riskstats)
> # Copy riskstats into etfenv
> etfenv$riskstats <- riskstats
> # Calculate the beta, alpha, Treynor ratio, and other performance
> capmstats <- PerformanceAnalytics::table.CAPM(Ra=retp[, symbolv],
                                           Rb=retp[, "VTI"], scale=

## Scraping S&P500 Stock Index Constituents From Websites

The *S&P500* index constituents change over time, and *Standard & Poor's* replaces companies that have decreased in capitalization with ones that have increased

The *S&P500* index may contain more than 500 stocks because some companies have several share classes of stock

The *S&P500* index constituents may be scraped from websites like Wikipedia, using dedicated packages.

The function getURL() from package RCurl downloads the html text data from an internet website URL.

The function readHTMLTable() from package XML extracts tables from html text data or from a remote URL, and returns them as a list of data frames or matrices.

readHTMLTable() can't parse secure URLs, so they
must first be downloaded using function getURL(), and
then parsed using readHTMLTable().

```
> library(RCurl) # Load package RCurl
> library(XML) # Load package XML
> # Download text data from URL
> sp500 <- getURL(
    "https://en.wikipedia.org/wiki/List_of_S%26P500_companies")
> # Extract tables from the text data
> sp500 <- readHTMLTable(sp500)
> str(sp500)
> # Extract colnames of data frames
> lapply(sp500, colnames)
> # Extract S&P500 constituents
> sp500 <- sp500[[1]]
> head(sp500)
> # Create valid R names from symbols containing "-" or "."characte
> sp500$namev <- gsub("-", "_", sp500$Ticker)
> sp500$namev <- gsub("[.]", "_", sp500$names)
```

file="/Users/jerzy/Develop/lecture\_slides/data/sp500\_Yahoo.csv"

> # Write data frame of S&P500 constituents to CSV file

> write.csv(sp500.

row.names=FALSE)

# Downloading S&P500 Time Series Data From Yahoo

Before time series data for the S&P500 index constituents can be downloaded from Yahoo, it's necessary to create valid names corresponding to symbols containing special characters like "-".

The function setSymbolLookup() creates a lookup table for *Yahoo* symbols, using valid names in R.

For example Yahoo uses the symbol "BRK-B", which isn't a valid name in R, but can be mapped to "BRK\_B", using the function setSymbolLookup().

```
> library(rutils) # Load package rutils
> # Load data frame of S&P500 constituents from CSV file
> sp500 <- read.csv(file="/Users/jerzy/Develop/lecture_slides/data/
> # Register symbols corresponding to R names
> for (indeks in 1:NROW(sp500)) {
    cat("processing: ", sp500$Ticker[indeks], "\n")
    setSymbolLookup(structure(
      list(list(name=sp500$Ticker[indeks])),
      names=sp500$names[indeks]))
+ } # end for
> sp500env <- new.env() # new environment for data
> # Remove all files (if necessary)
> rm(list=ls(sp500env), envir=sp500env)
> # Download data and copy it into environment
> rutils::get_data(sp500$names,
     env out=sp500env, startd="1990-01-01")
> # Or download in loop
> for (symboln in sp500$names) {
    cat("processing: ", symboln, "\n")
    rutils::get data(symboln.
     env_out=sp500env, startd="1990-01-01")
> save(sp500env, file="/Users/jerzy/Develop/lecture_slides/data/sp5
> chart_Series(x=sp500env$BRKB["2016/"],
         TA="add_Vo()", name="BRK-B stock")
```

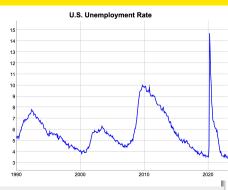

# Downloading FRED Time Series Data

FRED is a database of economic time series maintained by the Federal Reserve Bank of St. Louis: http://research.stlouisfed.org/fred2/

The function getSymbols() downloads time series data into the specified *environment*.

getSymbols() can download FRED data with the
argument "src" set to FRED.

If the argument "auto.assign" is set to FALSE, then getSymbols() returns the data, instead of assigning it silently.

- > # Download U.S. unemployment rate data
- > unrate <- quantmod::getSymbols("UNRATE",
- + auto.assign=FALSE, src="FRED")
- > # Plot U.S. unemployment rate data
- > dygraphs::dygraph(unrate["1990/"], main="U.S. Unemployment Rate")
- + dyOptions(colors="blue", strokeWidth=2)
- > # Or
- > quantmod::chart\_Series(unrate["1990/"], name="U.S. Unemployment R

## The Quandl Database

Quandl is a distributor of third party data, and offers several million financial, economic, and social datasets.

Much of the Quandl data is free, while premium data can be obtained under a temporary license.

Quandl provides online help and a guide to its datasets: https://www.guandl.com/help/r

https://www.quandi.com/neip/i

https://www.quandl.com/browse https:

nttps

//www.quandl.com/blog/getting-started-with-the-quandl-api https://www.guandl.com/blog/stock-market-data-guide

Quandl provides stock prices, stock fundamentals, financial ratios, zoo::indexes, options and volatility, earnings estimates, analyst ratings, etc.:

https://www.quandl.com/blog/api-for-stock-data

- > install.packages("devtools")
- > library(devtools)
  - > # Install package Quandl from github > install\_github("quandl/R-package")
- > library(Quandl) # Load package Quandl
- > # Register Quandl API key
- > Quandl.api\_key("pVJi9Nv3V8CD3Js5s7Qx")
- > # Get short description
- > packageDescription("Quandl")
- > # Load help page
  > help(package="Quand1")
- > # Remove Quandl from search path
- > # Remove quandi from search path > detach("package:Quandl")

Quandl has developed an R package called  $\mathit{Quandl}$  that allows downloading data from Quandl directly into R.

To make more than 50 downloads a day, you need to register your *Quandl API key* using the function Quandl.api\_key(),

# Downloading Time Series Data from Quandl

Quandl data can be downloaded directly into R using the function Quandl().

The dots "..." argument of the Quandl() function

accepts additional parameters to the Quandl API,

Quandl datasets have a unique Quandl code in the format "database/ticker", which can be found on the Quandl website for that dataset:

https://www.quandl.com/data/WIKI?keyword=aapl

 $\it{WIKI}$  is a user maintained free database of daily prices for 3,000 U.S. stocks,

https://www.quandl.com/data/WIKI

SEC is a free database of stock fundamentals extracted from SEC 10Q and 10K filings (but not harmonized),

https://www.quandl.com/data/SEC

RAYMOND is a free database of harmonized stock fundamentals, based on the SEC database,

https://www.quandl.com/data/RAYMOND-Raymond https://www.quandl.com/data/RAYMOND-Raymond?keyword=aapl

```
> library(rutils) # Load package rutils
> # Download EOD AAPL prices from WIKI free database
> pricev <- Quandl(code="WIKI/AAPL",
    type="xts", startd="1990-01-01")
> x11(width=14, height=7)
> chart_Series(pricev["2016", 1:4], name="AAPL OHLC prices")
> # Add trade volume in extra panel
> add_TA(pricev["2016", 5])
> # Download euro currency rates
> pricev <- Quandl(code="BNP/USDEUR".
      startd="2013-01-01".
      endd="2013-12-01", type="xts")
> # Download multiple time series
> pricev <- Quandl(code=c("NSE/OIL", "WIKI/AAPL"),
      startd="2013-01-01", type="xts")
> # Download AAPL gross profits
> prof_it <- Quandl("RAYMOND/AAPL_GROSS_PROFIT_Q", type="xts")
> chart Series(prof it, name="AAPL gross profits")
> # Download Hurst time series
> pricey <- Quandl(code="PE/AAPL HURST".
      startd="2013-01-01", type="xts")
> chart_Series(pricev["2016/", 1], name="AAPL Hurst")
```

# Stock Index and Instrument Metadata on Quandl

Instrument metadata specifies properties of instruments, like its currency, contract size, tick value, delievery months, start date, etc.

Quandl provides instrument metadata for stock indices. futures, and currencies:

https://www.quandl.com/blog/useful-listv

Quandl also provides constituents for stock indices, for example the S&P500. Dow Jones Industrial Average. NASDAQ Composite, FTSE 100, etc.

```
> # Load S&P500 stock Quandl codes
> sp500 <- read.csv(
+ file="/Users/jerzy/Develop/lecture_slides/data/sp500_quandl.csv
> # Replace "-" with "_" in symbols
> sp500$free_code <- gsub("-", "_", sp500$free_code)
> head(sp500)
> # vector of symbols in sp500 frame
> tickers <- gsub("-", "_", sp500$ticker)
```

- > # Or > tickers <- matrix(unlist(
- strsplit(sp500\$free\_code, split="/"),
- use.names=FALSE), ncol=2, byrow=TRUE)[, 2] > # Or
- > tickers <- do\_call\_rbind(
- strsplit(sp500\$free\_code, split="/"))[, 2]

# Downloading Multiple Time Series from Quandl

Time series data for a portfolio of stocks can be downloaded by performing a loop over the function Quand1() from package Quandl.

The assign() function assigns a value to an object in a specified *environment*, by referencing it using a character string (name).

> chart Series(x=sp500eny\$XOM["2016/"], TA="add Vo()", name="XOM st

> library(Quand1)

# Downloading Futures Time Series from Quandl

QuandI provides the Wiki CHRIS Database of time series of prices for 600 different futures contracts.

The Wiki CHRIS Database contains daily OHLC prices for continuous futures contracts

A continuous futures contract is a time series of prices obtained by chaining together prices from consecutive futures contracts

The data is curated by the Quandl community from data provided by the CME, ICE, LIFFE, and other exchanges.

The Quandl codes are specified as CHRIS/{EXCHANGE}\_{CODE}{DEPTH}, where {DEPTH} is the depth of the chained contract.

The chained front month contracts have depth 1, the back month contracts have depth 2, etc.

The continuous front and back month contracts allow building continuous futures curves.

Quandl data can be downloaded directly into R using the function Quand1().

```
> # Register Quandl API key
> Quandl.api_key("pVJi9Nv3V8CD3Js5s7Qx")
> # Download E-mini S&P500 futures prices
> pricev <- Quandl(code="CHRIS/CME ES1".
    type="xts", startd="1990-01-01")
```

- > pricev <- pricev[, c("Open", "High", "Low", "Last", "Volume")] > colnames(pricev)[4] <- "Close"
- > # Plot the prices > x11(width=5, height=4) # Open x11 for plotting > chart Series(x=pricev["2008-06/2009-06"].
- TA="add Vo()", name="S&P500 Futures") > # Plot dygraph
  - > dygraphs::dygraph(pricev["2008-06/2009-06", -5], main="S&P500 Futures") %>%
- dvCandlestick()

For example, the Quandl code for the continuous E-mini S&P500 front month futures is CHRIS/CME ES1 while for the back month it's CHRIS/CME\_ES2, for the second back month it's CHRIS/CME\_ES3. etc.

The Quandl code for the E-mini Oil futures is CHRIS/CME\_QM1, for the E-mini euro FX futures is CHRIS/CME\_E71. etc.

## Downloading VIX Futures Files from CBOE

The CFE (CBOE Futures Exchange) provides daily CBOE Historical Data for Volatility Futures, including the *VIX* futures.

The CBOE data incudes *OHLC* prices and also the *settlement* price (in column "Settle").

The settlement price is usually defined as the weighted average price (WAP) or the midpoint price, and is different from the Close price.

The settlement price is used for calculating the daily mark to market (value) of the futures contract.

Futures exchanges require that counterparties exchange (settle) the *mark to market* value of the futures contract daily, to reduce counterparty default risk.

The function download.file() downloads files from the internet.

The function tryCatch() executes functions and expressions, and handles any exception conditions produced when they are evaluated.

```
> # Read CBOE futures expiration dates
> datev <- read.csv(file="/Users/jerzy/Develop/lecture_slides/data/
   row.names=1)
> dirn <- "/Users/jerzy/Develop/data/vix_data"
> dir.create(dirn)
> symbolv <- rownames(datev)
> filens <- file.path(dirn, paste0(symbolv, ".csv"))
> log_file <- file.path(dirn, "log_file.txt")
> cboe_url <- "https://markets.cboe.com/us/futures/market_statistic
> urls <- pasteO(cboe_url, datev[, 1])
> # Download files in loop
> for (it in seq_along(urls)) {
     tryCatch( # Warning and error handler
   download.file(urls[it],
           destfile=filens[it], quiet=TRUE),
+ # Warning handler captures warning condition
+ warning=function(msg) {
   cat(paste0("Warning handler: ", msg, "\n"), file=log_file, appe
+ }, # end warning handler
+ # Error handler captures error condition
+ error=function(msg) {
   cat(paste0("Error handler: ", msg, "\n"), append=TRUE)
+ }. # end error handler
+ finally=cat(paste0("Processing file name = ", filens[it], "\n"),
     ) # end tryCatch
+ } # end for
```

# Downloading VIX Futures Data Into an Environment

The function quantmod::getSymbols() with the parameter src="cfe" downloads CFE data into the specified environment. (But this requires first loading the package qmao.)

Currently quantmod::getSymbols() doesn't download the most recent data.

- > # Create new environment for data
- > vix\_env <- new.env()
- > # Download VIX data for the months 6, 7, and 8 in 2018
- > library(qmao) > quantmod::getSymbols("VX", Months=1:12,
- Years=2018, src="cfe", auto.assign=TRUE, env=vix\_env)
- > # Or
- > qmao::getSymbols.cfe(Symbols="VX", Months=6:8, Years=2018, env=vix\_env,
  - verbose=FALSE, auto.assign=TRUE)
- > # Calculate the classes of all the objects
- > # In the environment vix\_env
- > unlist(eapply(vix\_env, function(x) {class(x)[1]}))
- > class(vix\_env\$VX\_M18)
- > colnames(vix\_env\$VX\_M18)
- > # Save the data to a binary file called "vix\_cboe.RData". > save(vix\_env,
- + file="/Users/jerzy/Develop/data/vix\_data/vix\_cboe.RData")

# Kernel Density of Asset Returns

The kernel density is proportional to the number of data points close to a given point.

The kernel density is analogous to a histogram, but it provides more detailed information about the distribution of the data.

The smoothing kernel K(x) is a symmetric function which decreases with the distance x.

The kernel density  $d_r$  at a point r is equal to the sum over the kernel function K(x):

$$d_r = \sum_{j=1}^n K(r - r_j)$$

# 

```
> # Plot the kernel density

> madv <- mad(retp)

> plot(retp) densi, xlim=c(-5*madv, 5*madv),

+ t="1", col="blue", lwd=3,

+ xlab="returns", ylab="density",

+ main="Density of VII Returns")
```

> dens1 <- sapply(1:nrows, function(it) {
+ sum(dnorm(retp-retp[it], sd=bwidth))</pre>

+ })/nrows # end sapply

# Kernel Density Using the Function density()

The function density() calculates a kernel estimate of the probability density for a sample of data.

The parameter *smoothing bandwidth* is the standard deviation of the smoothing kernel K(x).

The function density() returns a vector of densities at equally spaced points, not for the original data points.

The function approx() interpolates a vector of data into another vector.

The function lines() draws a line through specified points.

```
> densev <- density(retp, bw=bwidth)
> NROW(densv, xlim=c(-5*madv, 5*madv),

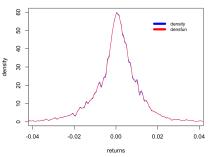

* xlab="returns", ylab="density",

+ col="blue", lud*3, main="Density of VTI Returns")
> # Interpolate the densv vector into returns
> densv <- approx(densy$x, densy$x, xout=retp)
```

> # Calculate the kernel density using density()

> all.equal(densy\$x, retp)

#### Density of VTI Returns

+ lwd=6, bg="white", col=c("blue", "red"))

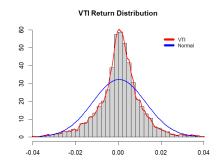

#### Distribution of Asset Returns

Asset returns are usually not normally distributed and they exhibit *leptokurtosis* (large kurtosis, or fat tails).

The function hist() calculates and plots a histogram, and returns its data *invisibly*.

The parameter breaks is the number of cells of the histogram.

The function lines() draws a line through specified points.

- > # Plot histogram
- > histp <- hist(retp, breaks=100, freq=FALSE,
- + xlim=c(-5\*madv, 5\*madv), xlab="", ylab="",
- + main="VTI Return Distribution")
- > # Draw kernel density of histogram
  > lines(densv, col="red", lwd=2)
- > # Add density of normal distribution
- > curve(expr=dnorm(x, mean=mean(retp), sd=sd(retp)),
- + add=TRUE, lwd=2, col="blue")
- > # Add legend
- > legend("topright", inset=0.05, cex=0.8, title=NULL,
- + leg=c("VTI", "Normal"), bty="n", y.intersp=0.4,
- + lwd=6, bg="white", col=c("red", "blue"))

# The Quantile-Quantile Plot

A  $\mathit{Quantile-Quantile}$  ( $\mathit{Q-Q}$ ) plot is a plot of points with the same  $\mathit{quantiles}$ , from two probability distributions.

If the two distributions are similar then all the points in the Q-Q plot lie along the diagonal.

The VTI Q-Q plot shows that the VTI return distribution has fat tails.

The p-value of the Shapiro-Wilk test is very close to zero, which shows that the VTI returns are very unlikely to be normal.

The function shapiro.test() performs the Shapiro-Wilk test of normality.

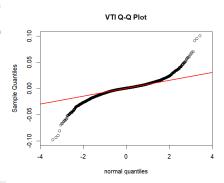

The function qqnorm() produces a normal Q-Q plot.

The function qqline() fits a line to the normal quantiles.

<sup>+</sup> xlab="Normal Quantiles")

- > # Perform Shapiro-Wilk test
- > shapiro.test(retp)

<sup>&</sup>gt; # Fit a line to the normal quantiles

<sup>&</sup>gt; qqline(retp, col="red", lwd=2)

# Boxplots of Distributions of Values

Box-and-whisker plots (boxplots) are graphical representations of a distribution of values.

The bottom and top box edges (hinges) are equal to the first and third quartiles, and the box width is equal to the interquartile range (IQR).

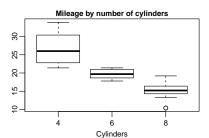

The nominal range is equal to 1.5 times the IQR above and below the box hinges.

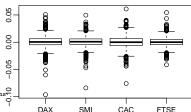

The whiskers are dashed vertical lines representing values beyond the first and third quartiles, but within the nominal range.

The whiskers end at the last values within the nominal range, while the open circles represent outlier values beyond the nominal range.

The function boxplot() has two methods: one for formula objects (for categorical variables), and another for data frames.

- > # Boxplot method for formula > boxplot(formula=mpg ~ cyl, data=mtcars, main="Mileage by number of cylinders",
- xlab="Cylinders", ylab="Miles per gallon") > # Boxplot method for data frame of EuStockMarkets percentage returns
- > boxplot(x=diff(log(EuStockMarkets)))

# Higher Moments of Asset Returns

The estimators of moments of a probability distribution are given by:

Sample mean: 
$$\bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i$$

Sample variance: 
$$\hat{\sigma}^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2$$

With their expected values equal to the population mean and standard deviation:

$$\mathbb{E}[\bar{\mathbf{x}}] = \mu \quad \text{and} \quad \mathbb{E}[\hat{\sigma}] = \sigma$$

The sample skewness (third moment):

$$\varsigma = \frac{n}{(n-1)(n-2)} \sum_{i=1}^{n} \left(\frac{x_i - \bar{x}}{\hat{\sigma}}\right)^3$$

The sample kurtosis (fourth moment):

$$\kappa = \frac{n(n+1)}{(n-1)(n-2)(n-3)} \sum_{i=1}^{n} (\frac{x_i - \bar{x}}{\hat{\sigma}})^4$$

The normal distribution has skewness equal to 0 and kurtosis equal to 3.

Stock returns typically have negative skewness and kurtosis much greater than 3.

- > # Calculate VTI percentage returns
- > retp <- na.omit(rutils::etfenv\$returns\$VTI)
- > # Number of observations
- > nrows <- NROW(retp)
- > # Mean of VTT returns
- > retm <- mean(retp) > # Standard deviation of VTI returns
- > stdev <- sd(retp)
- > # Skewness of VTI returns
- > nrows/((nrows-1)\*(nrows-2))\*sum(((retp retm)/stdev)^3)
- > # Kurtosis of VTI returns > nrows\*(nrows+1)/((nrows-1)^3)\*sum(((retp - retm)/stdev)^4)
- > # Random normal returns
- > retp <- rnorm(nrows, sd=stdev)
- > # Mean and standard deviation of random normal returns > retm <- mean(retp)
- > stdev <- sd(retp)
- > # Skewness of random normal returns
- > nrows/((nrows-1)\*(nrows-2))\*sum(((retp retm)/stdev)^3)
- > # Kurtosis of random normal returns
- > nrows\*(nrows+1)/((nrows-1)^3)\*sum(((retp retm)/stdev)^4)

> calc mom(retp. moment=4)

# Functions for Calculating Skew and Kurtosis

R provides an easy way for users to write functions.

The function calc\_skew() calculates the skew of

returns, and calc\_kurt() calculates the kurtosis.

Functions return the value of the last expression that is evaluated.

```
> # calc skew() calculates skew of returns
> calc_skew <- function(retp) {
    retp <- na.omit(retp)
    sum(((retp = mean(retp))/sd(retp))^3)/NROW(retp)
+ } # end calc skew
> # calc kurt() calculates kurtosis of returns
> calc kurt <- function(retp) {
    retp <- na.omit(retp)
    sum(((retp = mean(retp))/sd(retp))^4)/NROW(retp)
+ } # end calc kurt
> # Calculate skew and kurtosis of VTI returns
> calc skew(retp)
> calc kurt(retp)
> # calc mom() calculates the moments of returns
> calc_mom <- function(retp, moment=3) {
    retp <- na.omit(retp)
    sum(((retp - mean(retp))/sd(retp))^moment)/NROW(retp)
+ } # end calc mom
> # Calculate skew and kurtosis of VTI returns
> calc mom(retp. moment=3)
```

#### Standard Errors of Estimators

Statistical estimators are functions of samples (which are random variables), and therefore are themselves random variables

The *standard error* (SE) of an estimator is defined as its *standard deviation* (not to be confused with the *population standard deviation* of the underlying random variable).

For example, the *standard error* of the estimator of the mean is equal to:

$$\sigma_{\mu} = \frac{\sigma}{\sqrt{n}}$$

Where  $\sigma$  is the *population standard deviation* (which is usually unkown).

The estimator of this standard error is equal to:

$$SE_{\mu} = \frac{\hat{\sigma}}{\sqrt{n}}$$

where:  $\hat{\sigma}^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2$  is the sample standard deviation (the estimator of the population standard deviation).

- > # Initialize the random number generator
- > set.seed(1121, "Mersenne-Twister", sample.kind="Rejection")
- > # Sample from Standard Normal Distribution
- > nrows <- 1000
- > datav <- rnorm(nrows)
- > # Sample mean
- > mean(datav)
- > # Sample standard deviation
- > sd(datav)
- > # Standard error of sample mean
- > sd(datav)/sqrt(nrows)

# Normal (Gaussian) Probability Distribution

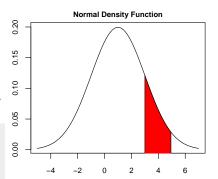

The Normal (Gaussian) probability density function is given by:

$$\phi(x,\mu,\sigma) = \frac{e^{-(x-\mu)^2/2\sigma^2}}{\sigma\sqrt{2\pi}}$$

The Standard Normal distribution  $\phi(0,1)$  is a special case of the Normal  $\phi(\mu,\sigma)$  with  $\mu=0$  and  $\sigma=1$ .

The function  ${\tt dnorm}()$  calculates the  ${\tt Normal}$  probability density.

```
> xvar <- seq(-5, 7, length=100)
> yvar <- dnorm(xvar, mean=1.0, sd=2.0)
> plot(xvar, yvar, type="1", lty="solid", xlab="", ylab="")
> title(main="Normal Density Function", line=0.5)
> startp <- 3; endd <- 5  # Set lower and upper bounds
> # Set polygon base
> subv <- ((xvar >= startp) & (xvar <= endd))
> polygon(c(startp, xvar[subv], endd), # Draw polygon
```

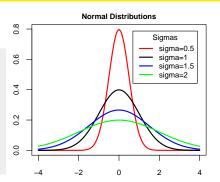

Jerzy Pawlowski (NYU Tandon)

c(-1, yvar[subv], -1), col="red")

# Normal (Gaussian) Probability Distributions

Plots of several *Normal* distributions with different values of  $\sigma$ , using the function curve() for plotting functions given by their name.

```
> sigmavs <- (c0.5, 1, 1.5, 2) # Sigma values
> # Create plot colors
> colorv <- c("red", "black", "blue", "green")
> # Create legend labels
> labelv <- paste("sigma", sigmavs, sep="=")
> for (it in 1:4) { # Plot four curves
+ curve(expr=dnorm(x, sd=sigmavs[it]),
+ xlim=c(-4, 4), xlab="", ylab="", lwd=2,
+ col=colorv[it], add=as.logical(it-1))
+ } # end for
> # Add title
> title(main="Normal Distributions", line=0.5)
> # Add legend
> legend("topright", inset=0.05, title="Sigmas", y.intersp=0.4,
+ labelv, cex=0.8, lwd=2, lty=1, bty="n", col=colorv)
```

## Student's t-distribution

Let  $z_1, \ldots, z_{\nu}$  be independent standard normal random variables, with sample mean:  $\bar{z} = \frac{1}{i!} \sum_{i=1}^{\nu} z_i$  $(\mathbb{E}[\bar{z}] = \mu)$  and sample variance:

$$\hat{\sigma}^2 = \frac{1}{\nu - 1} \sum_{i=1}^{\nu} (z_i - \bar{z})^2$$

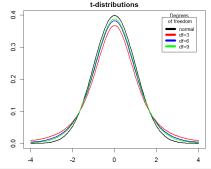

Then the random variable (t-ratio):

$$t = \frac{\bar{z} - \mu}{\hat{\sigma} / \sqrt{\nu}}$$

Follows the *t-distribution* with  $\nu$  degrees of freedom. with the probability density function:

$$f(t) = \frac{\Gamma((\nu+1)/2)}{\sqrt{\pi\nu} \, \Gamma(\nu/2)} \, (1 + t^2/\nu)^{-(\nu+1)/2}$$

- > degf <- c(3, 6, 9) # Df values

#### Mixture Models of Returns

Mixture models are produced by randomly sampling data from different distributions.

The mixture of two normal distributions with different variances produces a distribution with leptokurtosis (large kurtosis, or fat tails).

Student's t-distribution has fat tails because the sample variance in the denominator of the t-ratio is variable

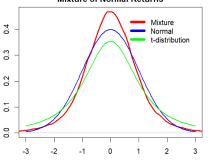

The time-dependent volatility of asset returns is referred to as heteroskedasticity.

Random processes with heteroskedasticity can be considered a type of mixture model.

The heteroskedasticity produces leptokurtosis (large kurtosis, or fat tails).

- > # Mixture of two normal distributions with sd=1 and sd=2 > nrows <- 1e5
- > retp <- c(rnorm(nrows/2), 2\*rnorm(nrows/2))
- > retp <- (retp-mean(retp))/sd(retp)
- > # Kurtosis of normal
- > calc\_kurt(rnorm(nrows))
- > # Kurtosis of mixture
- > calc\_kurt(retp)
- > # Or
- > nrows\*sum(retp^4)/(nrows-1)^2

#### Mixture of Normal Returns

- legend=c("Mixture", "Normal", "t-distribution"), y.intersp=0.4,
- + col=c("red", "blue", "green"))

## Non-standard Student's t-distribution

The non-standard Student's t-distribution has the probability density function:

$$f(t) = \frac{\Gamma((\nu+1)/2)}{\sqrt{\pi\nu} \, \sigma \, \Gamma(\nu/2)} \, (1 + (\frac{t-\mu}{\sigma})^2/\nu)^{-(\nu+1)/2}$$

It has non-zero mean equal to the location parameter  $\mu$ , and a standard deviation proportional to the scale parameter  $\sigma$ .

```
> dev.new(width=6, height=5, noRStudioGD=TRUE)
> # x11(width=6, height=5)
> # Define density of non-standard t-distribution
> tdistr <- function(x, dfree, locv=0, scalev=1) {
   dt((x-locv)/scalev, df=dfree)/scalev
+ } # end tdistr
> # Or
> tdistr <- function(x, dfree, locv=0, scalev=1) {
   gamma((dfree+1)/2)/(sqrt(pi*dfree)*gamma(dfree/2)*scalev)*
      (1+((x-locy)/scaley)^2/dfree)^(-(dfree+1)/2)
+ } # end tdistr
```

> # Calculate vector of scale values > scalev <- c(0.5, 1.0, 2.0)

> colorv <- c("blue", "black", "red")

> labelv <- paste("scale", format(scalev, digits=2), sep="=")

> # Plot three t-distributions > for (it in 1:3) {

# The Shapiro-Wilk Test of Normality

The Shapiro-Wilk test is designed to test the null hypothesis that a sample:  $\{x_1, \ldots, x_n\}$  is from a normally distributed population.

The test statistic is equal to:

$$W = \frac{\left(\sum_{i=1}^{n} a_i x_{(i)}\right)^2}{\sum_{i=1}^{n} (x_i - \bar{x})^2}$$

Where the:  $\{a_1, \ldots, a_n\}$  are proportional to the *order* statistics of random variables from the normal distribution.

 $x_{(k)}$  is the k-th order statistic, and is equal to the k-th smallest value in the sample:  $\{x_1, \ldots, x_n\}$ .

The *Shapiro-Wilk* statistic follows its own distribution, and is less than or equal to 1.

The *Shapiro-Wilk* statistic is close to 1 for samples from normal distributions.

The *p*-value for *VTI* returns is extremely small, and we conclude that the *null hypothesis* is FALSE, and the *VTI* returns are not from a normally distributed population.

The *Shapiro-Wilk* test is not reliable for large sample sizes, so it's limited to less than 5000 sample size.

- > # Calculate VTI percentage returns
- > library(rutils)
- > retp <- as.numeric(na.omit(rutils::etfenv\$returns\$VTI))[1:499]
- > # Reduce number of output digits

# The Jarque-Bera Test of Normality

The Jarque-Bera test is designed to test the null hypothesis that a sample:  $\{x_1,\ldots,x_n\}$  is from a normally distributed population.

The test statistic is equal to:

$$JB = \frac{n}{6}(\varsigma^2 + \frac{1}{4}(\kappa - 3)^2)$$

Where the skewness and kurtosis are defined as:

$$\varsigma = \frac{1}{n} \sum_{i=1}^{n} \left( \frac{x_i - \bar{x}}{\hat{\sigma}} \right)^3 \qquad \kappa = \frac{1}{n} \sum_{i=1}^{n} \left( \frac{x_i - \bar{x}}{\hat{\sigma}} \right)^4$$

The Jarque-Bera statistic asymptotically follows the chi-squared distribution with 2 degrees of freedom.

The *Jarque-Bera* statistic is small for samples from normal distributions.

The p-value for VTI returns is extremely small, and we conclude that the  $null\ hypothesis$  is FALSE, and the VTI returns are not from a normally distributed population.

# The Kolmogorov-Smirnov Test for Probability Distributions

The *Kolmogorov-Smirnov* test *null hypothesis* is that two samples:  $\{x_1, \ldots, x_n\}$  and  $\{y_1, \ldots, y_n\}$  were obtained from the same probability distribution.

The Kolmogorov-Smirnov statistic depends on the maximum difference between two empirical cumulative distribution functions (cumulative frequencies):

$$D = \sup_{i} |P(x_i) - P(y_i)|$$

The function ks.test() performs the *Kolmogorov-Smirnov* test and returns the statistic and its *p*-value *invisibly*.

The second argument to ks.test() can be either a numeric vector of data values, or a name of a cumulative distribution function.

The Kolmogorov-Smirnov test can be used as a goodness of fit test, to test if a set of observations fits a probability distribution.

- > # KS test for normal distribution
- > ks\_test <- ks.test(rnorm(100), pnorm)
- > ks\_test\$p.value
- > # KS test for uniform distribution
- > ks.test(runif(100), pnorm)

  > ks.test(rnorm(100), rnorm(100, mean=1.0))
- > # KS test (Inorm(100), Inorm(100, mean=1.0))
  > # KS test for two different normal distributions
- > # AS test for two different normal distrib > ks.test(rnorm(100), rnorm(100, sd=2.0))
- > # KS test for VTI returns vs normal distribution
- > retp <- as.numeric(na.omit(rutils::etfenv\$returns\$VTI))
- > retp <- (retp mean(retp))/sd(retp)
- > ks.test(retp, pnorm)

# Chi-squared Distribution

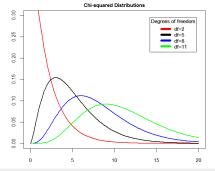

Let  $z_1, \ldots, z_k$  be independent standard *Normal* random variables.

Then the random variable  $X = \sum_{i=1}^k z_i^2$  is distributed according to the *Chi-squared* distribution with k degrees of freedom:  $X \sim \chi_k^2$ , and its probability density function is given by:

$$f(x) = \frac{x^{k/2-1} e^{-x/2}}{2^{k/2} \Gamma(k/2)}$$

The *Chi-squared* distribution with k degrees of freedom has mean equal to k and variance equal to 2k.

# The Chi-squared Test for the Goodness of Fit

Goodness of Fit tests are designed to test if a set of observations fits an assumed theoretical probability distribution.

The *Chi-squared* test tests if a frequency of counts fits the specified distribution.

The *Chi-squared* statistic is the sum of squared differences between the observed frequencies  $o_i$  and the theoretical frequencies  $p_i$ :

$$\chi^2 = N \sum_{i=1}^n \frac{(o_i - p_i)^2}{p_i}$$

Where N is the total number of observations.

The *null hypothesis* is that the observed frequencies are consistent with the theoretical distribution.

The function chisq.test() performs the *Chi-squared* test and returns the statistic and its *p*-value *invisibly*.

The parameter breaks in the function hist() should be chosen large enough to capture the shape of the frequency distribution.

- > # Observed frequencies from random normal data
- > histp <- hist(rnorm(1e3, mean=0), breaks=100, plot=FALSE)
- > countsn <- histp\$counts

## The Likelihood Function of Student's t-distribution

The non-standard Student's t-distribution is:

$$f(t) = \frac{\Gamma((\nu+1)/2)}{\sqrt{\pi \nu} \sigma \Gamma(\nu/2)} \left(1 + \left(\frac{t-\mu}{\sigma}\right)^2/\nu\right)^{-(\nu+1)/2}$$

It has non-zero mean equal to the location parameter  $\mu$ , and a standard deviation proportional to the scale parameter  $\sigma$ .

The negative logarithm of the probability density is equal to:

$$\begin{split} -\log(f(t)) &= -\log(\frac{\Gamma((\nu+1)/2)}{\sqrt{\pi\nu}}) + \log(\sigma) + \\ &\frac{\nu+1}{2}\log(1+(\frac{t-\mu}{\sigma})^2/\nu) \end{split}$$

The *likelihood* function  $\mathcal{L}(\theta|\bar{x})$  is a function of the model parameters  $\theta$ , given the observed values  $\bar{x}$ , under the model's probability distribution  $f(x|\theta)$ :

$$\mathcal{L}(\theta|x) = \prod_{i=1}^{n} f(x_i|\theta)$$

- > # Objective function from function dt()
- > likefun <- function(par, dfree, datav) { -sum(log(dt(x=(datav-par[1])/par[2], df=dfree)/par[2]))
- # end likefun
- > # Demonstrate equivalence with log(dt())
- > likefun(c(1, 0.5), 2, 2:5)
- > -sum(log(dt(x=(2:5-1)/0.5, df=2)/0.5))> # Objective function is negative log-likelihood
- > likefun <- function(par, dfree, datay) {
- sum(-log(gamma((dfree+1)/2)/(sqrt(pi\*dfree)\*gamma(dfree/2))) + log(par[2]) + (dfree+1)/2\*log(1+((datay-par[1])/par[2])^2/dfr
- + } # end likefun

The likelihood function measures how likely are the parameters, given the observed values  $\bar{x}$ . The maximum-likelihood estimate (MLE) of the

parameters are those that maximize the likelihood function:

$$\theta_{MLE} = \arg\max_{\theta} \mathcal{L}(\theta|x)$$

In practice the logarithm of the likelihood  $log(\mathcal{L})$  is maximized, instead of the likelihood itself.

# Fitting Asset Returns into Student's t-distribution

The function fitdistr() from package MASS fits a univariate distribution to a sample of data, by performing maximum likelihood optimization.

The function fitdistr() performs a maximum likelihood optimization to find the non-standardized Student's *t-distribution* location and scale parameters.

- > # Calculate VTI percentage returns
- > retp <- as.numeric(na.omit(rutils::etfenv\$returns\$VTI))
- > # Fit VTI returns using MASS::fitdistr()

## The Student's t-distribution Fitted to Asset Returns

Asset returns typically exhibit negative skewness and large kurtosis (leptokurtosis), or fat tails.

Stock returns fit the non-standard *t-distribution* with 3 degrees of freedom quite well.

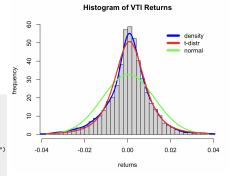

The function hist() calculates and plots a histogram, and returns its data *invisibly*.

The parameter breaks is the number of cells of the histogram.

> dev.new(width=6, height=5, noRStudioGD=TRUE)

> # x11(width=6, height=5)

```
> # Plot histogram of VTI returns
> madv <- mad(retp)
> histp <- hist(retp, col="lightgrey",
   xlab="returns", breaks=100, xlim=c(-5*madv, 5*madv),
 ylab="frequency", freq=FALSE, main="Histogram of VTI Returns")

## Goodness of Fit of Student's t-distribution Fitted to Asset Returns

The Q-Q plot illustrates the relative distributions of two samples of data.

The Q-Q plot shows that stock returns fit the non-standard t-distribution with 3 degrees of freedom auite well.

The function qqplot() produces a Q-Q plot for two samples of data.

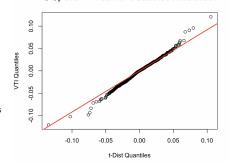

The function ks.test() performs the Kolmogorov-Smirnov test for the similarity of two distributions.

The null hypothesis of the Kolmogorov-Smirnov test is that the two samples were obtained from the same probability distribution.

The Kolmogorov-Smirnov test rejects the null hypothesis that stock returns follow closely the non-standard t-distribution with 3 degrees of freedom.

- > # Calculate sample from non-standard t-distribution with df=3 > datat <- locv + scalev\*rt(NROW(retp), df=3)
- > # Q-Q plot of VTI Returns vs non-standard t-distribution

- pt((x-locv)/scalev, df=dfree)
- > # KS test for VTI returns vs cumulative t-distribution
- > ks.test(sample(retp, replace=TRUE), ptdistr, dfree=3, locv=locv,

## Leptokurtosis Fat Tails of Asset Returns

The probability under the *normal* distribution decreases exponentially for large values of *x*:

$$\phi(x) \propto e^{-x^2/2\sigma^2}$$
 (as  $|x| \to \infty$ )

This is because a normal variable can be thought of as the sum of a large number of independent binomial variables of equal size.

So large values are produced only when all the contributing binomial variables are of the same sign, which is very improbable, so it produces extremely low tail probabilities (thin tails),

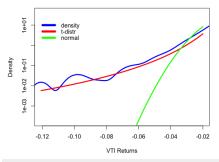

But in reality, the probability of large negative asset returns decreases much slower, as the negative power of the returns (fat tails).

The probability under Student's *t-distribution* decreases as a power for large values of *x*:

$$f(x) \propto |x|^{-(\nu+1)}$$
 (as  $|x| \to \infty$ )

This is because a *t-variable* can be thought of as the sum of normal variables with different volatilities (different sizes).

#### Fat Left Tail of VTI Returns (density in log scale)

- > # Plot log density of VTI returns

lwd=6, lty=1, col=c("blue", "red", "green"))

## **Trading Volumes**

The average trading volumes have increased significantly since the 2008 crisis, mostly because of high frequency trading (HFT).

Higher levels of volatility coincide with higher trading volumes

The time-dependent volatility of asset returns (heteroskedasticity) produces their fat tails (leptokurtosis).

```
> # Calculate VTI returns and trading volumes
> ohlc <- rutils::etfenv$VTI
> closep <- drop(coredata(quantmod::Cl(ohlc)))
> retp <- rutils::diffit(log(closep))

# Asset Returns in Trading Time

The time-dependent volatility of asset returns (heteroskedasticity) produces their fat tails (leptokurtosis).

If asset returns were measured at fixed intervals of trading volumes (trading time instead of clock time), then the volatility would be lower and less time-dependent.

The asset returns can be adjusted to *trading time* by dividing them by the *square root of the trading volumes*, to obtain scaled returns over equal trading volumes.

The scaled returns have a more positive *skewness* and a smaller *kurtosis* than unscaled returns.

```
> # Scale the returns using volume clock to trading time
> retsc <- ifelse(volumv > 0, sqrt(volumr)*retp/sqrt(volumv), 0)
> retsc <- sd(retp)*retsc/sd(retsc)
> # retsc <- ifelse(volumv > 1e4, retp/volumv, 0)
> # Calculate moments of scaled returns
> nrous <- NROW(retp)
> sapply(list(retp=retp, retsc=retsc),

> perfstats <- unclass(data(
```

- package="PerformanceAnalytics"))\$results[, -(1:2)]
- > apply(perfstats, 1, paste, collapse=" ")
- > # Load "managers" data set
- > data(managers)
  - > class(managers)
    > dim(managers)
- > head(managers, 3)

#### Plots of Cumulative Returns

The function chart.CumReturns() from package PerformanceAnalytics plots the cumulative returns of a time series of returns.

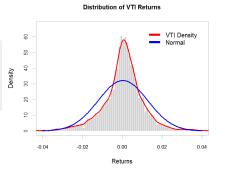

```
> # Load package "PerformanceAnalytics"
> library(PerformanceAnalytics)
> # Calculate ETF returns
> retp <- rutils::enfenu%returns[, c("VTI", "DBC", "IEF")]
> retp <- na.omit(retp)
> # Plot cumulative ETF returns
> x11(width=6, height=5)
> chart.CumReturns(retp, lwd=2, ylab="",
+ legend.loc="topleft", main="ETF Cumulative Returns")
```

### The Distribution of Asset Returns

The function chart.Histogram() from package PerformanceAnalytics plots the histogram (frequency distribution) and the density of returns.

```
> retp <- na.omit(rutils::etfenv$returns$VTI)
> chart.Histogram(retp, xlimec(-0.04, 0.04),
+ colorset = c("lightgray", "red", "blue"), lwd=3,
+ main=paste("Distribution of", colnames(retp), "Returns"),
+ methods = c("add.density", "add.normal"))
> legend("topright", inset=0.05, bty="n", y.intersp=0.4,
+ lege=("VII Density", "Normal"),
```

+ lwd=6, ltv=1, col=c("red", "blue"))

## Boxplots of Returns

The function chart.Boxplot() from package PerformanceAnalytics plots a box-and-whisker plot for a distribution of returns.

The function chart.Boxplot() is a wrapper and calls the function graphics::boxplot() to plot the box plots.

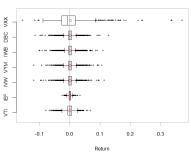

A box plot (box-and-whisker plot) is a graphical display of a distribution of data:

The box represents the upper and lower quartiles, The vertical lines (whiskers) represent values beyond

the quartiles, Open circles represent values beyond the nominal range (outliers).

- > retp <- rutils::etfenv\$returns[,
  + c("VTI", "IEF", "IVW", "VYM", "IWB", "DBC", "VXX")]
  > x11(width=6, height=5)
- > chart.Boxplot(names=FALSE, retp)
- > par(cex.lab=0.8, cex.axis=0.8)
- > axis(side=2, at=(1:NCOL(retp))/7.5-0.05,labels=colnames(retp))

#### Return Distribution Comparison

## The Median Absolute Deviation Estimator of Dispersion

The Median Absolute Deviation (MAD) is a nonparametric measure of dispersion (variability), defined using the median instead of the mean:

$$MAD = median(abs(x_i - median(x)))$$

The advantage of MAD is that it's always well defined. even for data that has infinite variance.

The MAD for normally distributed data is equal to  $\Phi^{-1}(0.75) \cdot \hat{\sigma} = 0.6745 \cdot \hat{\sigma}.$ 

The function mad() calculates the MAD and divides it by  $\Phi^{-1}(0.75)$  to make it comparable to the standard deviation

For normally distributed data the MAD has a larger standard error than the standard deviation.

```
> # Simulate normally distributed data
> nrows <- 1000
> datav <- rnorm(nrows)</pre>
> sd(datav)
> mad(datav)
> median(abs(datav - median(datav)))
> median(abs(datay - median(datay)))/gnorm(0.75)
> # Bootstrap of sd and mad estimators
> bootd <- sapply(1:10000, function(x) {
    samplev <- datav[sample.int(nrows, replace=TRUE)]
    c(sd=sd(samplev), mad=mad(samplev))
+ }) # end sapply
> bootd <- t(bootd)
> # Analyze bootstrapped variance
> head(bootd)
> sum(is.na(bootd))
> # Means and standard errors from bootstrap
> apply(bootd, MARGIN=2, function(x)
+ c(mean=mean(x), stderror=sd(x)))
> # Parallel bootstrap under Windows
> library(parallel) # Load package parallel
> ncores <- detectCores() - 1 # Number of cores
> compclust <- makeCluster(ncores) # Initialize compute cluster
> bootd <- parLapply(compclust, 1:10000,
    function(x, datav) {
      samplev <- datav[sample.int(nrows, replace=TRUE)]
      c(sd=sd(samplev), mad=mad(samplev))
    }, datav=datav) # end parLapply
> # Parallel bootstrap under Mac-OSX or Linux
> bootd <- mclapply(1:10000, function(x) {
      samplev <- datav[sample.int(nrows, replace=TRUE)]
```

> bootd <- rutils::do call(rbind, bootd)

> apply(bootd, MARGIN=2, function(x)

c(sd=sd(samplev), mad=mad(samplev)) }, mc.cores=ncores) # end mclapply > stopCluster(compclust) # Stop R processes over cluster

> bootd <- mclapply(1:10000, function(x) {

}, mc.cores=ncores) # end mclapply

> # Means and standard errors from bootstrap

> bootd <- rutils::do call(rbind, bootd)

> apply(bootd, MARGIN=2, function(x)
+ c(mean=mean(x), stderror=sd(x)))

c(sd=sd(samplev), mad=mad(samplev))

### The Median Absolute Deviation of Asset Returns

For normally distributed data the  $\ensuremath{\textit{MAD}}$  has a larger standard error than the standard deviation.

But for distributions with fat tails (like asset returns), the standard deviation has a larger standard error than the *MAD*.

The *bootstrap* procedure performs a loop, which naturally lends itself to parallel computing.

The function makeCluster() starts running R processes on several CPU cores under *Windows*.

The function parLapply() is similar to lapply(), and performs loops under *Windows* using parallel computing on several CPU cores.

The R processes started by makeCluster() don't inherit any data from the parent R process.

Therefore the required data must be either passed into parLapply() via the dots "..." argument, or by calling the function clusterExport().

The function mclapply() performs loops using parallel computing on several CPU cores under *Mac-OSX* or *Linux*.

The function stopCluster() stops the R processes running on several CPU cores.

```
> # Calculate VTI returns
> retp <- na.omit(rutils::etfenv$returns$VTI)
> nrows <- NROW(retp)
> sd(retp)
> mad(retp)
> # Bootstrap of sd and mad estimators
> bootd <- sapply(1:10000, function(x) {
   samplev <- retp[sample.int(nrows, replace=TRUE)]
   c(sd=sd(samplev), mad=mad(samplev))
+ }) # end sapply
> bootd <- t(bootd)
> # Means and standard errors from bootstrap
> 100*apply(bootd, MARGIN=2, function(x)
+ c(mean=mean(x), stderror=sd(x)))
> # Parallel bootstrap under Windows
> library(parallel) # Load package parallel
> ncores <- detectCores() - 1 # Number of cores
> compclust <- makeCluster(ncores) # Initialize compute cluster
> clusterExport(compclust, c("nrows", "returns"))
> bootd <- parLapply(compclust, 1:10000,
   function(x) {
     samplev <- retp[sample.int(nrows, replace=TRUE)]
     c(sd=sd(sampley), mad=mad(sampley))
   }) # end parLapply
> # Parallel bootstrap under Mac-OSX or Linux
```

samplev <- retp[sample.int(nrows, replace=TRUE)]

> stopCluster(compclust) # Stop R processes over cluster

75 / 88

## The Downside Deviation of Asset Returns

Some investors argue that positive returns don't represent risk, only those returns less than the target rate of return  $r_t$ .

The Downside Deviation (semi-deviation)  $\sigma_d$  is equal to the standard deviation of returns less than the target rate of return  $r_t$ :

$$\sigma_d = \sqrt{\frac{1}{n} \sum_{i=1}^{n} ([r_i - r_t]_-)^2}$$

The function DownsideDeviation() from package PerformanceAnalytics calculates the downside deviation, for either the full time series

(method="full") or only for the subseries less than the target rate of return  $r_t$  (method="subset").

```
> library(PerformanceAnalytics)
> # Define target rate of return of 50 bps
```

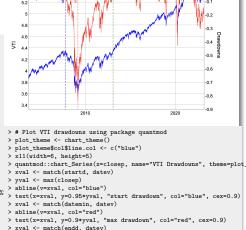

- > targetr <- 0.005
- > # Calculate the full downside returns
- > retsub <- (retp targetr) > retsub <- ifelse(retsub < 0, retsub, 0)
- > nrows <- NROW(retsub)
- > # Calculate the downside deviation > all.equal(sqrt(sum(retsub^2)/nrows).
- drop(DownsideDeviation(retp, MAR=targetr, method="full")))
- > # Calculate the subset downside returns
- > retsub <- (retp targetr) > retsub <- retsub[retsub < 0]
- > nrows <- NROW(retsub)
- > # Calculate the downside deviation
- > all.equal(sqrt(sum(retsub^2)/nrows).
  - drop(DownsideDeviation(retp, MAR=targetr, method="subset")))

#### Drawdown Risk

A drawdown is the drop in prices from their historical peak, and is equal to the difference between the prices minus the cumulative maximum of the prices.

Drawdown risk determines the risk of liquidation due to stop loss limits.

```
> # Calculate time series of VTI drawdowns
> closep <- log(quantmod::Cl(rutils::etfenv$VTI))
> drawdns <- (closep - cummax(closep))
> # Extract the date index from the time series closep
> datev <- zoo::index(closep)
> # Calculate the maximum drawdown date and depth
> indexmin <- which.min(drawdns)
> datemin <- datev[indexmin]
> maxdd <- drawdns[datemin]
> # Calculate the drawdown start and end dates
> startd <- max(datev[(datev < datemin) & (drawdns == 0)])
> endd <- min(datev[(datev > datemin) & (drawdns == 0)])
> # dygraph plot of VTI drawdowns
> datav <- cbind(closep, drawdns)
> colnamev <- c("VTI", "Drawdowns")
> colnames(datay) <- colnamey
> dygraphs::dygraph(datav, main="VTI Drawdowns") %>%
   dyAxis("y", label=colnamev[1], independentTicks=TRUE) %>%
   dyAxis("y2", label=colnamev[2],
    valueRange=(1.2*range(drawdns)+0.1), independentTicks=TRUE) %
   dySeries(name=colnamev[1], axis="y", col="blue") %>%
   dySeries(name=colnamev[2], axis="y2", col="red") %>%
   dyEvent(startd, "start drawdown", col="blue") %>%
   dvEvent(datemin, "max drawdown", col="red") %>%
   dvEvent(endd, "end drawdown", col="green")
```

VTI Drawdowns

- VTI - Drawdowns

> abline(v=xval, col="green")

> text(x=xval, v=0.85\*vval, "end drawdown", col="green", cex=0.9)

## Drawdown Risk Using PerformanceAnalytics::table.Drawdowns()

The function table.Drawdowns() from package PerformanceAnalytics calculates a data frame of drawdowns.

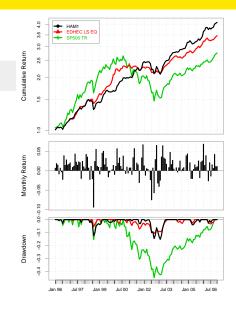

- > library(xtable)
- > library(PerformanceAnalytics)
- > closep <- log(quantmod::Cl(rutils::etfenv\$VTI))
- > retp <- rutils::diffit(closep)
- > # Calculate table of VTI drawdowns
- > tablev <- PerformanceAnalytics::table.Drawdowns(retp, geometric=FALSE)
- > # Convert dates to strings
- > tablev <- cbind(sapply(tablev[, 1:3], as.character), tablev[, 4:7])
- > # Print table of VTI drawdowns
- > print(xtable(tablev), comment=FALSE, size="tiny", include.rownames=FALSE)

From	Trough	То	Depth	Length	To Trough	Recovery
2007-10-10	2009-03-09	2012-03-13	-0.57	1115.00	355.00	760.00
2001-06-06	2002-10-09	2004-11-04	-0.45	858.00	336.00	522.00
2020-02-20	2020-03-23	2020-08-12	-0.18	122.00	23.00	99.00
2022-01-04	2022-10-12	2023-12-18	-0.10	492.00	195.00	297.00
2018-09-21	2018-12-24	2019-04-23	-0.10	146.00	65.00	81.00

## PerformanceSummary Plots

The function charts.PerformanceSummary() from package *PerformanceAnalytics* plots three charts: cumulative returns, return bars, and drawdowns, for time series of returns.

- > data(managers)
- > charts.PerformanceSummary(ham1,
- main="", lwd=2, ylog=TRUE)

#### The Loss Distribution of Asset Returns

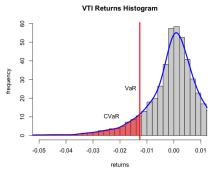

The distribution of returns has a long left tail of negative returns representing the risk of loss.

The Value at Risk (VaR) is equal to the quantile of returns corresponding to a given confidence level  $\alpha$ .

The Conditional Value at Risk ( $\rm CVaR)$  is equal to the average of negative returns less than the  $\rm VaR.$ 

The function hist() calculates and plots a histogram, and returns its data *invisibly*.

The function density() calculates a kernel estimate of the probability density for a sample of data.

```
> # Plot density
> lines(densv, lwd=3, col="blue")
> # Plot line for VaR
> abline(v=varisk, col="red", lwd=3)
> text(z=varisk, y=25, labels="VaR", lwd=2, pos=2)
> # Plot polygon shading for CVaR
> text(z=1.5*varisk, y=10, labels="CVaR", lwd=2, pos=2)
> varmax <- -0.06
> varmax <- (densv$x < varisk) & (densv$x > varmax)
> polygon(c(varmax, densv$x[rangev], varisk), + c(0. densv$x -0.00; 0.0.05), border=NA)
```

September 3, 2024

> # Calculate VTI percentage returns
> retp <- na.omit(rutils::etfenv\$returns\$VTI)</pre>

> densy <- density(retp, adjust=1.5)

> # Calculate density

## Value at Risk (VaR)

The Value at Risk (VaR) is equal to the quantile of returns corresponding to a given confidence level  $\alpha$ :

$$\alpha = \int_{-\infty}^{\mathrm{VaR}(\alpha)} \mathsf{f}(r) \, \mathrm{d}r$$

Where f(r) is the probability density (distribution) of returns.

At a high confidence level, the value of VaR is subject to estimation error, and various numerical methods are used to approximate it.

The function quantile() calculates the sample quantiles. It uses interpolation to improve the accuracy. Information about the different interpolation methods can be found by typing ?quantile.

A simpler but less accurate way of calculating the quantile is by sorting and selecting the data closest to the quantile.

The function VaR() from package PerformanceAnalytics calculates the Value at Risk using several different methods.

- > # Calculate VTI percentage returns
- > retp <- na.omit(rutils::etfenv\$returns\$VTI)
  > nrows <- NROW(retp)</pre>
- > confl <- 0.05
- > # Calculate VaR approximately by sorting
- > sortv <- sort(as.numeric(retp))
- > cutoff <- round(confl\*nrows)
  > varisk <- sortv[cutoff]
- > # Calculate VaR as quantile
- > varisk <- quantile(retp, probs=confl)
- > # PerformanceAnalytics VaR
- > PerformanceAnalytics::VaR(retp, p=(1-confl), method="historical")
- > all.equal(unname(varisk),
- + as.numeric(PerformanceAnalytics::VaR(retp,
  - + p=(1-confl), method="historical")))

# Conditional Value at Risk (CVaR)

The Conditional Value at Risk (CVaR) is equal to the average of negative returns less than the VaR:

$$CVaR = \frac{1}{\alpha} \int_0^{\alpha} VaR(\rho) d\rho$$

The Conditional Value at Risk is also called the Expected Shortfall (ES), or the Expected Tail Loss (ETL).

The function ETL() from package PerformanceAnalytics calculates the Conditional Value at Risk using several different methods.

- > # Calculate VaR as quantile
- > varisk <- quantile(retp, confl)
- > # Calculate CVaR as expected loss
  > cvar <- mean(retp[retp <= varisk])</pre>
- > # PerformanceAnalytics VaR
- > PerformanceAnalytics::ETL(retp, p=(1-confl), method="historical")
- > all.equal(unname(cvar),
  + as.numeric(PerformanceAnalytics::ETL(retp,
- + p=(1-confl), method="historical")))

Sharne

Skewness Kurtosis

#### Risk and Return Statistics

The function table.Stats() from package PerformanceAnalytics calculates a data frame of risk and return statistics of the return distributions.

- > # Calculate the risk-return statistics
- > riskstats <-
- PerformanceAnalytics::table.Stats(rutils::etfenv\$returns)
- > class(riskstats)
- > # Transpose the data frame
- > riskstats <- as.data.frame(t(riskstats))
- > # Add Name column
- > riskstats\$Name <- rownames(riskstats)
- > # Add Sharpe ratio column
- > riskstats\$"Arithmetic Mean" <-
- sapply(rutils::etfenv\$returns, mean, na.rm=TRUE)
- > riskstats\$Sharpe <sqrt(252)\*riskstats\$"Arithmetic Mean"/riskstats\$Stdev
- > # Sort on Sharpe ratio
- > riskstats <- riskstats[order(riskstats\$Sharpe, decreasing=TRUE),

		Snarpe	Skewness	Kurtosis

#### Investor Risk and Return Preferences

Investors typically prefer larger *odd moments* of the return distribution (mean, skewness), and smaller *even moments* (variance, kurtosis).

But positive skewness is often associated with lower returns, which can be observed in the *VIX* volatility ETFs, *VXX* and *SVXY*.

The VXX ETF is long the VIX index (effectively long an option), so it has positive skewness and small kurtosis, but negative returns (it's short market risk).

Since the VXX is effectively long an option, it pays option premiums so it has negative returns most of the time, with isolated periods of positive returns when markets drop.

The *SVXY* ETF is short the *VIX* index, so it has negative skewness and large kurtosis, but positive returns (it's long market risk).

Since the SVXY is effectively short an option, it earns option premiums so it has positive returns most of the time, but it suffers sharp losses when markets drop.

	Sharpe	Skewness	Kurtosis
VXX	-1.176	1.18	6.12
SVXY	0.173	-18.24	673.25

- > # dygraph plot of VXX versus SVXY
- > pricev <- na.omit(rutils::etfenv\$prices[, c("VXX", "SVXY")])
- > pricev <- pricev["2017/"]
- > colnamev <- c("VXX", "SVXY")</pre>
- > colnames(pricev) <- colnamev
- > dygraphs::dygraph(pricev, main="Prices of VXX and SVXY") %>%
  + dyAxis("y", label=colnamev[1], independentTicks=TRUE) %>%
- + dyAxis("y2", label=colnamev[2], independentTicks=TRUE) %>%
  - + dySeries(name=colnamev[1], axis="y", strokeWidth=2, col="blue")
- + dySeries(name=colnamev[1], axis="y", strokeWidth=2, col="blue")
  + dySeries(name=colnamev[2], axis="y2", strokeWidth=2, col="green
- + dySeries(name=colnamev[2], axis="y2", strokeWidth=2, col="green
  + dyLegend(show="always", width=300) %% dyLegend(show="always",
- + dyLegend(show="always", width=300)

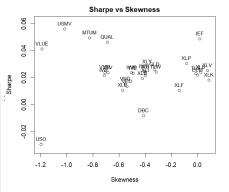

### Skewness and Return Tradeoff

Similarly to the VXX and SVXY, for most other ETFs positive skewness is often associated with lower returns.

Some of the exceptions are bond ETFs (like *IEF*), which have both non-negative skewness and positive returns.

Another exception are commodity ETFs (like USO oil), which have both negative skewness and negative returns.

```
> # Remove VIX volatility ETF data
> riskstats <- riskstats[-match(c("VXX", "SVXY"), riskstats$Name),
> # Plot scatterplot of Sharpe vs Skewness
> plot(Sharpe ~ Skewness, data=riskstats,
      vlim=1.1*range(riskstats$Sharpe),
      main="Sharpe vs Skewness")
> # Add labels
> text(x=riskstats$Skewness, y=riskstats$Sharpe,
      labels=riskstats$Name, pos=3, cex=0.8)
> # Plot scatterplot of Kurtosis vs Skewness
> x11(width=6, height=5)
> par(mar=c(4, 4, 2, 1), oma=c(0, 0, 0, 0))
> plot(Kurtosis ~ Skewness, data=riskstats,
      vlim=c(1, max(riskstats$Kurtosis)).
      main="Kurtosis vs Skewness")
  # Add lahels
> text(x=riskstats$Skewness, v=riskstats$Kurtosis,
```

labels=riskstats\$Name, pos=1, cex=0.5)

## Risk-adjusted Return Measures

The Sharpe ratio  $S_r$  is equal to the excess returns (in excess of the risk-free rate  $r_f$ ) divided by the standard deviation  $\sigma$  of the returns:

$$\mathrm{S_r} = \frac{E[r-r_f]}{\sigma}$$

The Sortino ratio  $\mathrm{So}_{\mathrm{r}}$  is equal to the excess returns divided by the downside deviation  $\sigma_d$  (standard deviation of returns that are less than a target rate of return  $r_{\mathrm{t}}$ ):

$$So_{r} = \frac{E[r - r_{t}]}{\sigma_{d}}$$

The Calmar ratio  $\mathrm{C_r}$  is equal to the excess returns divided by the maximum drawdown  $\mathrm{DD}$  of the returns:

$$C_{\rm r} = \frac{E[r - r_f]}{{
m DD}}$$

The <code>Dowd ratio</code>  $D_{\rm r}$  is equal to the excess returns divided by the <code>Value at Risk</code> (VaR) of the returns:

$$D_{\rm r} = \frac{E[r - r_f]}{{\rm VaR}}$$

The Conditional Dowd ratio  $\mathrm{Dc_r}$  is equal to the excess returns divided by the Conditional Value at Risk ( $\mathrm{CVaR}$ ) of the returns:

$$Dc_{r} = \frac{E[r - r_{f}]}{CVaR}$$

```
> library(PerformanceAnalytics)
> retp <- rutils::etfenv$returns[, c("VTI", "IEF")]
> retp <- na.omit(retp)
> # Calculate the Sharpe ratio
> confl <- 0.05
> PerformanceAnalytics::SharpeRatio(retp, p=(1-confl),
    method="historical")
> # Calculate the Sortino ratio
> PerformanceAnalytics::SortinoRatio(retp)
> # Calculate the Calmar ratio
> PerformanceAnalytics::CalmarRatio(retp)
> # Calculate the Dowd ratio
> PerformanceAnalytics::SharpeRatio(retp, FUN="VaR",
    p=(1-confl), method="historical")
> # Calculate the Dowd ratio from scratch
> varisk <- sapply(retp, quantile, probs=confl)
> -sapply(retp, mean)/varisk
> # Calculate the Conditional Dowd ratio
> PerformanceAnalytics::SharpeRatio(retp, FUN="ES",
    p=(1-confl), method="historical")
> # Calculate the Conditional Dowd ratio from scratch
> cvar <- sapply(retp, function(x) {
    mean(x[x < quantile(x, confl)])
```

+ })

> -sapply(retp, mean)/cvar

## Risk of Aggregated Stock Returns

Stock returns aggregated over longer holding periods are closer to normally distributed, and their skewness, kurtosis, and tail risks are significantly lower than for daily returns.

Stocks become less risky over longer holding periods. so investors may choose to own a higher percentage of stocks, provided they hold them for a longer period of time

```
> # Calculate VTI daily percentage returns
> retp <- na.omit(rutils::etfenv$returns$VTI)
> nrows <- NROW(retp)
> # Bootstrap aggregated monthly VTI returns
> holdp <- 22
> reta <- sqrt(holdp)*sapply(1:nrows, function(x) {
      mean(retp[sample.int(nrows, size=holdp, replace=TRUE)])
+ }) # end sapply
> # Calculate mean, standard deviation, skewness, and kurtosis
> datav <- cbind(retp, reta)
> colnames(datav) <- c("VTI", "Agg")
> sapply(datay, function(x) {
   # Standardize the returns
   meanv <- mean(x); stdev <- sd(x); x <- (x - meanv)/stdev
   c(mean=meanv, stdev=stdev, skew=mean(x^3), kurt=mean(x^4))
+ }) # end sapply
> # Calculate the Sharpe and Dowd ratios
> confl <- 0.02
> ratiom <- sapply(datav, function(x) {
   stdev \leftarrow sd(x)
  varisk <- unname(quantile(x, probs=confl))</pre>
   cvar <- mean(x[x < varisk])

# Homework Assignment

### Required

• Study all the lecture slides in FRE7241\_Lecture\_1.pdf, and run all the code in FRE7241\_Lecture\_1.R,

#### Recommended

• Read the documentation for packages rutils.pdf and HighFreq.pdf,
