> datetime <- 0

> datetime # "Date" object

> structure(10000.25, class="Date")

Date Objects

R has a Date class for date objects (but without time).

The function as.Date() parses character strings and coerces numeric objects into Date objects.

R stores Date objects as the number of days since the $\it epoch$ (January 1, 1970).

The function difftime() calculates the difference between Date objects, and returns a time interval object of class difftime.

The "+" and "-" arithmetic operators and the "<" and ">" logical comparison operators are overloaded to allow these operations directly on Date objects.

numeric year-fraction dates can be coerced to Date objects using the functions attributes() and structure().

```
> Sys.Date() # Get today's date
> as.Date(1e3) # Coerce numeric into date object
> datetime <- as.Date("2014-07-14") # "%Y-%m-%d" or "%Y/%m/%d"
> datetime > class(datetime) # Date object
> as.Date("07-14-2014", "%m-%d-%Y") # Specify format
> datetime + 20 # Add 20 days
> # Extract internal representation to integer
> as.numeric(datetime)
> datep( - as.Date("07/14/2013", "%m/%d/%Y")
> datep
> # Difference between dates
> difftime(datetime, datep, units="weeks")
> weekdays(datetime) # Get day of the week
> # Coerce numeric into date-times
```

> attributes(datetime) <- list(class="Date")

> structure(0, class="Date") # "Date" object

POSIXct Date-time Objects

The POSIXct class in R represents *date-time* objects, that can store both the date and time.

The *clock time* is the time (number of hours, minutes and seconds) in the local *time zone*.

The moment of time is the clock time in the UTC time zone.

POSIXct objects are stored as the number of seconds that have elapsed since the *epoch* (January 1, 1970) in the UTC *time zone*.

POSIXct objects are stored as the moment of time, but are printed out as the clock time in the local time zone.

A clock time together with a time zone uniquely specifies a moment of time.

The function as.POSIXct() can parse a character string (representing the *clock time*) and a *time zone* into a POSIXct object.

POSIX is an acronym for "Portable Operating System Interface".

- > datetime <- Sys.time() # Get today's date and time > datetime
- > class(datetime) # POSIXct object
- > # POSIXct stored as integer moment of time
- > as.numeric(datetime)
- > # Parse character string "%Y-%m-%d %H:%M:%S" to POSIXct object > datetime <- as.POSIXct("2014-07-14 13:30:10")
- > # Different time zones can have same clock time
- > as.POSIXct("2014-07-14 13:30:10", tz="America/New York")
- > as.POSIXct("2014-07-14 13:30:10", tz="UTC")
- > # Format argument allows parsing different date-time string forma
 > as.POSIXct("07/14/2014 13:30:10". format="%m/%d/%Y %H:%M:%S".
 - tz="America/New York")

Operations on POSIXct Objects

The "+" and "-" arithmetic operators are overloaded to allow addition and subtraction operations on POSIXct objects.

The "<" and ">" logical comparison operators are also overloaded to allow direct comparisons between POSIXct objects.

Operations on POSIXct objects are equivalent to the same operations on the internal integer representation of POSIXct (number of seconds since the *epoch*).

Subtracting POSIXct objects creates a time interval object of class difftime.

The method seq.POSIXt creates a vector of POSIXct date-times

- > # Same moment of time corresponds to different clock times
- > timeny <- as.POSIXct("2014-07-14 13:30:10", tz="America/New_York"
 > timeldn <- as.POSIXct("2014-07-14 13:30:10", tz="UTC")</pre>
- > # Add five hours to POSIXct
- > timeny + 5*60*60
- > # Subtract POSIXct
- > timeny timeldn
- > class(timeny timeldn)
- > # Compare POSIXct > timeny > timeldn
- > # Create vector of POSIXct times during trading hours
- > timev <- seq(
- + from=as.POSIXct("2014-07-14 09:30:00", tz="America/New_York"),
- + to=as.POSIXct("2014-07-14 16:00:00", tz="America/New_York"),
- + by="10 min")
- > head(timev, 3) > tail(timev, 3)

Moment of Time and Clock Time

as.POSIXct() can also coerce integer objects into POSIXct, given an origin in time.

The same *moment of time* corresponds to different *clock times* in different *time zones*.

The same *clock times* in different *time zones* correspond to different *moments of time*.

- > # POSIXct is stored as integer moment of time
- > datetimen <- as.numeric(datetime)
- \gt # Same moment of time corresponds to different clock times
- > as.POSIXct(datetimen, origin="1970-01-01", tz="America/New_York")
- > as.POSIXct(datetimen, origin="1970-01-01", tz="UTC")
 > # Same clock time corresponds to different moments of time
- > # Same clock time corresponds to different moments of time
 > as.POSIXct("2014-07-14 13:30:10", tz="America/New_York") -
- + as.POSIXct("2014-07-14 13:30:10", tz="UTC")
- > # Add 20 seconds to POSIXct
- > datetime + 20

Methods for Manipulating POSIXct Objects

The generic function format() formats R objects for printing and display.

The method format.POSIXct() parses POSIXct objects into a character string representing the clock time in a given time zone.

The method as.POSIXct.Date() parses Date objects into POSIXct, and assigns to them the *moment of time* corresponding to midnight UTC.

POSIX is an acronym for "Portable Operating System Interface".

- > datetime # POSIXct date and time
- > # Parse POSIXct to string representing the clock time
- > format(datetime)
- > class(format(datetime)) # Character string
- > # Get clock times in different time zones
- > format(datetime, tz="America/New_York")
- > format(datetime, tz="UTC")
- > # Format with custom format strings
 > format(datetime, "%m/%Y")
- > format(datetime, "%m-%d-%Y %H hours")
- > # Trunc to hour
- > format(datetime, "%m-%d-%Y %H:00:00")
- > # Date converted to midnight UTC moment of time > as.POSIXct(Sys.Date())
- > as.POSIXct(as.numeric(as.POSIXct(Sys.Date())),
- > as.PUSIACt(as.numeric(as.PUSIACt(Sys.Date())),
 + origin="1970-01-01",
 - tz="UTC")

POSIX1t Date-time Objects

The POSIX1t class in R represents *date-time* objects, that are stored internally as a list.

The function as .POSIX1t() can parse a character string (representing the *clock time*) and a *time zone* into a POSIX1t object.

The method format.POSIX1t() parses POSIX1t objects into a character string representing the *clock time* in a given *time zone*.

The function as.POSIX1t() can also parse a POSIXct object into a POSIX1t object, and as.POSIXct() can perform the reverse.

Adding a number to POSIX1t causes implicit coercion to POSIXct.

POSIXct and POSIXlt are two derived classes from the POSIXt class.

The methods round.POSIXt() and trunc.POSIXt() round and truncate POSIXt objects, and return POSIXlt objects.

- > # Parse character string "%Y-%m-%d %H:%M:%S" to POSIX1t object
- > datetime <- as.POSIX1t("2014-07-14 18:30:10")
- > datetime
- > class(datetime) # POSIX1t object
 > as.POSIXct(datetime) # Coerce to POSIXct object
- > # Extract internal list representation to vector
- > unlist(datetime)
- > datetime + 20 # Add 20 seconds
- > class(datetime + 20) # Implicit coercion to POSIXct
- > trunc(datetime, units="hours") # Truncate to closest hour
- > trunc(datetime, units="days") # Truncate to closest day > methods(trunc) # Trunc methods
- > trunc POSIXt

Time Zones and Date-time Conversion

 $\ensuremath{\textit{date-time}}$ objects require a $\ensuremath{\textit{time zone}}$ to be uniquely specified.

UTC stands for "Universal Time Coordinated", and is synonymous with GMT, but doesn't change with Daylight Saving Time.

 ${\tt EST}$ stands for "Eastern Standard Time", and is ${\tt UTC}$ - 5 hours.

EDT stands for "Eastern Daylight Time", and is \mathtt{UTC} - 4 hours.

The function Sys.setenv() can be used to set the default *time zone*, but the environment variable "TZ" must be capitalized.

- > # Set time-zone to UTC
- > Sys.setenv(TZ="UTC")
- > Sys.timezone() # Get time-zone
- > Sys.time() # Today's date and time > # Set time-zone back to New York
- > Sys.setenv(TZ="America/New_York")
- > Sys.time() # Today's date and time
- > # Standard Time in effect
- > as.POSIXct("2013-03-09 11:00:00", tz="America/New_York")
- > # Daylight Savings Time in effect
- > as.POSIXct("2013-03-10 11:00:00", tz="America/New_York")
- > datetime <- Sys.time() # Today's date and time
- > # Convert to character in different TZ
- > format(datetime, tz="America/New_York")
 > format(datetime, tz="UTC")
- > # Parse back to POSIXct
- > as.POSIXct(format(datetime, tz="America/New_York"))
- > # Difference between New_York time and UTC
- > as.POSIXct(format(Sys.time(), tz="UTC")) -
 - + as.POSIXct(format(Sys.time(), tz="America/New_York"))

Manipulating Date-time Objects Using *lubridate*

The package *lubridate* contains functions for manipulating POSIXct date-time objects.

The ymd(), dmy(), etc. functions parse character and numeric year-fraction dates into POSIXct objects.

functions extract date-time components.

The function decimal_date() converts POSIXct objects into numeric year-fraction dates.

The mday(), month(), year(), etc. accessor

The function date_decimal() converts numeric year-fraction dates into POSIXct objects.

tz="IITC")

> # Same moment of time
> datetime - with_tz(datetime, "UTC")
> # Different moments of time
> datetime - force tz(datetime, "UTC")

Time Zones Using *lubridate*

The package *lubridate* simplifies *time zone* calculations.

The package *lubridate* uses the *UTC time zone* as default.

The function with_tz() creates a date-time object with the same moment of time in a different *time zone*.

The function force_tz() creates a date-time object with the same clock time in a different *time zone*.

```
> datetime <- lubridate::ymd_hms(20140714142010,
+ tz="America/New_York")
> datetime
> # Get same moment of time in "UTC" time zone
> lubridate::with_tz(datetime, "UTC")
> as.POSIXct(format(datetime, tz="UTC"), tz="UTC")
> # Get same clock time in "UTC" time zone
> lubridate::force_tz(datetime, "UTC")
> as.POSIXct(format(datetime, tz="America/New_York"),
> as.POSIXct(format(datetime, tz="America/New_York"),
```

> datetime

Iubridate Time Span Objects

 $\ensuremath{\textit{lubridate}}$ has two time span classes: durations and periods.

durations specify exact time spans, such as numbers of seconds, hours, days, etc.

The functions ddays(), dyears(), etc. return

duration objects.

periods specify relative time spans that don't have a fixed length, such as months, years, etc.

periods account for variable days in the months, for Daylight Savings Time, and for leap years.

The functions days(), months(), years(), etc. return period objects.

```
> # Daylight Savings Time handling periods vs durations
> datetime <- as.POSIXct("2013-03-09 11:00:00", tz="America/New_Yori
> datetime
> datetime + lubridate::ddays(1) # Add duration
> datetime + lubridate::days(1) # Add period
> 
> leap_vear(2012) # Leap year
```

> datetime <- lubridate::dmy(01012012, tz="America/New_York")

> datetime + lubridate::dyears(1) # Add duration

> datetime + lubridate::years(1) # Add period

Adding Time Spans to Date-time Objects

periods allow calculating future dates with the same day of the month, or month of the year.

```
> datetime <- lubridate::ymd_hms(20140714142010, tz="America/New_Yo
> datetime
> # Add periods to a date-time
> c(datetime + lubridate::seconds(1), datetime + lubridate::minutes
+ datetime + lubridate::days(1), datetime + lubridate::months(1))
> # Create vectors of dates
> datetime <- lubridate::ymd(20140714, tz="America/New_York")
> datetime <- lubridate::ymd(20140714, tz="America/New_York")
> datetime + 0:2 * lubridate::months(1) # Monthly dates
> datetime + 0:2 * lubridate::months(2) # bi-monthly dates
> datetime + 0:2 * lubridate::months(2) # bi-monthly dates
> datetime + seq(0, 5, by=2) * lubridate::months(1)
> seq(datetime, length=3, by="2 months")
```

End-of-month Dates

Adding monthly periods can create invalid dates.

The operators $m+\$ and $m-\$ add or subtract monthly periods to account for the varible number of days per month.

This allows creating vectors of end-of-month dates.

- > # Adding monthly periods can create invalid dates
- > datetime <- lubridate::ymd(20120131, tz="America/New_York")
- > datetime + 0:2 * lubridate::months(1)
 > datetime + lubridate::months(1)
- > datetime + lubridate::months(2)
- > # Create vector of end-of-month dates
- > datetime %m-% lubridate::months(13:1)

Package RQuantLib Calendar Functions

The package RQuantLib is an interface to the QuantLib open source C/C++ library for quantitative finance, mostly designed for pricing fixed-income instruments and options.

The *QuantLib* library also contains calendar functions for determining holidays and business days in many different jurisdictions.

```
> library(RQuantLib) # Load RQuantLib
> # Create daily date series of class "Date"
> dates <- Sys.Date() + -5:2
> dates
> # Create Boolean vector of business days
> # Use RQuantLib calendar
> is_busday <- RQuantLib::isbusinessDay(
+ calendar="UnitedStates/GovernmentBond", dates)
> # Create daily series of business days
> bus_index <- dates[is_busday]
> bus index
> bus |
```

> Sys.setenv(TZ="UTC")
> as.POSIXct(head(qrtly_index, 4))

Review of Date-time Classes in R

The Date class from the base package is suitable for daily time series.

The POSIXct class from the base package is suitable

for intra-day time series.

The yearmon and yearqtr classes from the zoo package are suitable for quarterly and monthly time

series

Time Series Objects of Class ts

Time series are data objects that contain a date-time index and data associated with it.

The native time series class in R is ts.

ts time series are regular, i.e. they can only have an equally spaced date-time index.

ts time series have a numeric date-time index, usually encoded as a year-fraction, or some other unit, like number of months, etc.

For example the date "2015-03-31" can be encoded as a *year-fraction* equal to 2015.244.

The stats base package contains functions for manipulating time series objects of class ts.

The function ts() creates a ts time series from a numeric vector or matrix, and from the associated date-time information (the number of data per time unit: year, month, etc.).

The frequency argument is the number of observations per unit of time.

For example, if the *date-time* index is encoded as a year-fraction, then frequency=12 means 12 monthly data points per year.

```
> set.seed(1121, "Mersenne-Twister", sample.kind="Rejection")
> # Create daily time series ending today
> startd < decimal_date(Sys.Date()-6)
> endd <- decimal_date(Sys.Date())
> # Create vector of geometric Brownian motion
> datav <- exp(cumsum(rnorm(6)/100))
> tstep <- NRDW(datav)/(endd-startd)
> tseries <- ts(data-datav, start=startd, frequency=tstep)
> tseries # Display time series
> # Display index dates
> as.Date(date_decimal(zoo::coredata(time(tseries))))
> # bi=monthly geometric Brownian motion starting mid-1990
> tseries <- ts(data-exp(cumsum(rnorm(96)/100)),
```

frequency=6, start=1990.5)

Manipulating ts Time Series

ts time series don't store their date-time indices, and instead store only a "tsp" attribute that specifies the index start and end dates and its frequency.

The date-time index is calculated as needed from the "tsp" attribute.

The function time() extracts the date-time index of a ts time series object.

The function window() subsets the a ts time series object.

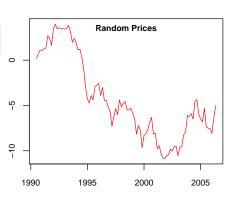

- > # Show some methods for class "ts"
- > matrix(methods(class="ts")[3:8], nco1=2)
- > # "tsp" attribute specifies the date-time index
- > attributes(tseries)
 > # Extract the index
- > # Extract the index
- > tail(time(tseries), 11)
 > # The index is equally spaced
- > diff(tail(time(tseries), 11))
- > # Subset the time series
 > window(tseries, start=1992, end=1992.25)

4 D > 4 P > 4 E > 4 E > E 990

Plotting ts Time Series Objects

The method plot.ts() plots ts time series objects.

```
> plot(tseries, type="1", # Create plot
+ col="red", lty="solid", xlab="", ylab="")
> title(main="Random Prices", line=-1) # Add title
```

EuStockMarkets Data

 $\ensuremath{\mathtt{R}}$ includes a number of base packages that are already installed and loaded.

datasets is a base package containing various datasets, for example: EuStockMarkets.

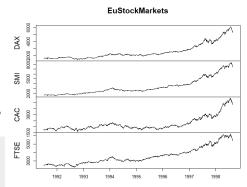

The EuStockMarkets dataset contains daily closing prices of european stock indices.

EuStockMarkets is a mts() time series object.

The EuStockMarkets date-time index is equally spaced (regular), so the year-fraction dates don't correspond to actual trading days.

```
> dim(EuStockMarkets)
> head(EuStockMarkets, 3) # Get first three rows
> # EuStockMarkets index is equally spaced
> diff(tail(time(EuStockMarkets), 11))
> # Plot all the columns in separate panels
> plot(EuStockMarkets, main="EuStockMarkets", xlab="")
```

> class(EuStockMarkets) # Multiple ts object

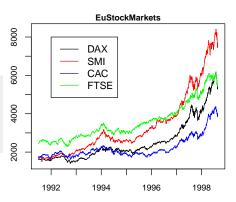

Plotting EuStockMarkets Data

The argument plot.type="single" for method plot.zoo() allows plotting multiple lines in a single panel (pane).

The four EuStockMarkets time series can be plotted in a single panel (pane).

```
> # Plot in single panel
> plot(EuStockMarkets, main="EuStockMarkets",
+ xlab="", ylab="", plot.type="single",
+ col=c("black", "red", "blue", "green"))
> # Add legend
> legend(x=1992, y=8000,
+ legend=colnames(EuStockMarkets),
+ col=c("black", "red", "blue", "green"),
+ tud=6. ltv=1)
```

zoo Time Series Objects

The package zoo is designed for managing *irregular* time series and ordered objects of class zoo.

Irregular time series have date-time indeices that aren't equally spaced (because of weekends, overnight hours, etc.).

The function zoo() creates a zoo object from a numeric vector or matrix, and an associated date-time index.

The zoo index is a vector of date-time objects, and can be from any date-time class.

The zoo class can manage *irregular* time series whose date-time index isn't equally spaced.

```
> library(zoo) # Load package zoo
> # Create zoo time series of random returns
> dates < - Sys.Date() + 0:3
> zoots <- zoo(rnorm(NROW(dates)), order.by=dates)
> zoots
> attributes(zoots)
> class(zoots) # Class "zoo"
> tail(zoots, 3) # Get last few elements
```

> cummin(cumsum(zoots))

Operations on zoo Time Series

The function zoo::coredata() extracts the data contained in zoo object, and returns a vector or matrix.

The function zoo::index() extracts the time index of a zoo object.

The function xts::.index() extracts the time index expressed in the number of seconds.

The functions start() and end() return the time index values of the first and last elements of a zoo object.

The functions cumsum(), cummax(), and cummin() return cumulative sums, minima and maxima of a zoo object.

```
> zoo::coredata(zoots) # Extract coredata
> zoo::index(zoots) # Extract time index
> start(zoots) # First date
> end(zoots) # Last date
> zoots[start(zoots)] # First element
> zoots[end(zoots)] # Last element
> zoo::coredata(zoots) <- rep(1, 4) # Replace coredata
> cumsum(zoots) # Cumulative sum
> cummay(conts))
```

> dim(zoots)
> attributes(zoots)

Single Column zoo Time Series

Single column zoo time series usually don't have a dimension attribute (they have a NULL dimension), and they don't have a column name, unlike multi-column zoo time series.

Single column zoo time series without a dimension attribute should be avoided, since they can cause hard to detect bugs.

If a single column zoo time series is created from a single column matrices, then it have a dimension attribute, and can be assigned a column name.

```
> zoots <- zoo(matrix(cumsum(rnorm(100)), nc=1),
+ order.by=seq(from=as.Date("2013-06-15"), by="day", len=100))
> colnames(zoots) <- "zoots"
> tail(zoots)
```

The lag() and diff() Functions

The method lag.zoo() returns a lagged version of a zoo time series, shifting the time index by "k" observations.

If "k" is positive, then lag.zoo() shifts values from the future to the present, and if "k" is negative then it shifts them from the past.

This is the opposite of what is usually considered as a positive *lag*.

A positive *lag* should replace the current value with values from the past (negative lags should replace with values from the future).

The method diff.zoo() returns the difference between a zoo time series and its proper lagged version from the past, given a positive *lag* value.

By default, the methods lag.zoo() and diff.zoo() omit any NA values they may have produced, and return shorter time series.

If the "na.pad" argument is set to TRUE, then they return time series of the same length, with NA values added where needed

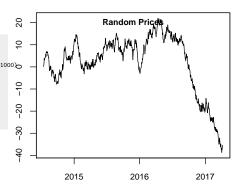

```
> zoo::coredata(zoots) <- (1:4)^2 # Replace coredata
> zoots
```

- > zoots > lag(zoots) # One day lag
- > lag(zoots, 2) # Two day lag
- > lag(zoots, k=-1) # Proper one day lag
- > diff(zoots) # Diff with one day lag
 > # Proper lag and original length
- > lag(zoots, -2, na.pad=TRUE)

Plotting zoo Time Series

zoo time series can be plotted using the generic function plot(), which dispatches the plot.zoo() method.

```
> set.seed(1121, "Mersenne-Twister", sample.kind="Rejection")
> library(zoo) # Load package zoo
> # Create index of daily dates
> dates <- seq(from=as.Date("2014-07-14"), by="day", length.out=1000)
> # Create vector of geometric Brownian motion
> datav <- exp(cumsum(rnorm(NROW(dates))/100))
> # Create zoo series of geometric Brownian motion
> zoots <- zoo(x=datav, order.by=dates)
> # Plot using plot.zoo method
> plot(zoots, xlab="", ylab="")
> title(main="Random Prices", line=-1) # Add title
```

Subsetting zoo Time Series

zoo time series can be subset in similar ways to matrices and ts time series.

The function window() can also subset zoo time series objects.

In addition, zoo time series can be subset using Date objects.

- > # Subset zoo as matrix
- > zoots[459:463, 1]
- > # Subset zoo using window()
 > window(zoots,
- + start=as.Date("2014-10-15"), + end=as.Date("2014-10-19"))
- + end=as.Date("2014-10-19"))
 > # Subset zoo using Date object
- > zoots[as.Date("2014-10-15")]

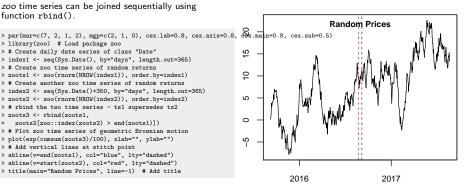

Jerzy Pawlowski (NYU Tandon)

Sequential Joining zoo Time Series

zoo time series can be joined sequentially using function rbind().

```
> library(zoo) # Load package zoo
> # Create daily date series of class "Date"
> index1 <- seq(Sys.Date(), by="days", length.out=365)
> # Create zoo time series of random returns
> zoots1 <- zoo(rnorm(NROW(index1)), order.bv=index1)
> # Create another zoo time series of random returns
> index2 <- seg(Sys.Date()+350, by="days", length.out=365)
> zoots2 <- zoo(rnorm(NROW(index2)), order.bv=index2)
> # rbind the two time series - ts1 supersedes ts2
> zoots3 <- rbind(zoots1.
    zoots2[zoo::index(zoots2) > end(zoots1)])
> # Plot zoo time series of geometric Brownian motion
> plot(exp(cumsum(zoots3)/100), xlab="", ylab="")
> # Add vertical lines at stitch point
> abline(v=end(zoots1), col="blue", lty="dashed")
> abline(v=start(zoots2), col="red", ltv="dashed")
```

> title(main="Random Prices", line=-1) # Add title

Merging zoo Time Series

zoo time series can be combined concurrently by joining their columns using function merge().

Function merge() is similar to function cbind().

If the all=TRUE option is set, then merge() returns the union of their dates, otherwise it returns their intersection.

The merge() operation can produce NA values.

- > # Create daily date series of class "Date"
 > index1 <- Sys.Date() + -3:1</pre>
- > # Create zoo time series of random returns
- > zoots1 <- zoo(rnorm(NROW(index1)), order.by=index1)
- > # Create another zoo time series of random returns
- > index2 <- Sys.Date() + -1:3
- > zoots2 <- zoo(rnorm(NROW(index2)), order.by=index2)
- > merge(zoots1, zoots2) # union of dates
- > # Intersection of dates
- > merge(zoots1, zoots2, all=FALSE)

Managing NA Values

Binding two time series that don't share the same time index produces NA values.

There are two dedicated functions for managing NA values in time series:

• stats::na.omit() removes whole rows of data

- stats::na.omit() removes whole rows of data containing NA values.
- zoo::na.locf() replaces NA values with the most recent non-NA values prior to it (locf stands for last observation carry forward).

Copying the last non-NA values forward causes less data loss than removing whole rows of data.

na.locf() with argument fromLast=TRUE operates in reverse order, starting from the end.

But copying values forward requires initializing the first row of data, to guarantee that initial NA values are also over-written.

The initial NA prices can be initialized to the first non-NA price in the future, which can be done by calling zoo::na.locf() with the argument fromLast=TRUE.

But the initial NA values in *returns* data should be initialized to *zero*, without carrying data backward from the future, to avoid data *snooping*.

```
> # Create matrix containing NA values
> matv <- sample(18)
> matv[sample(NROW(matv), 4)] <- NA
> matv <- matrix(matv, nc=3)
> # Replace NA values with most recent non-NA values
> zoo::na.locf(matv)
> rutils::na locf(matv)
> # Get time series of prices
> pricev <- mget(c("VTI", "VXX"), envir=rutils::etfenv)
> pricev <- lapply(pricev, quantmod::Cl)
> pricev <- rutils::do_call(cbind, pricev)
> sum(is.na(pricev))
> # Carry forward and backward non-NA prices
> pricev <- zoo::na.locf(pricev, na.rm=FALSE)
> pricev <- zoo::na.locf(pricev, na.rm=FALSE, fromLast=TRUE)
> sum(is.na(pricev))
> # Remove whole rows containing NA returns
> retp <- rutils::etfenv$returns
> sum(is.na(retp))
> retp <- na.omit(retp)
> # Or carry forward non-NA returns (preferred)
> retp <- rutils::etfenv$returns
> retp[1, is.na(retp[1, ])] <- 0
> retp <- zoo::na.locf(retp, na.rm=FALSE)
```

> sum(is.na(retp))

Managing NA Values in "xts" Time Series

The function na.locf.xts() from package xts is faster than zoo::na.locf(), but it only operates on time series of class "xts".

- > # Replace NAs in xts time series
- > pricev <- rutils::etfenv\$prices[, 1]
- > head(pricev)
- > sum(is.na(pricev))
- > library(quantmod)
- > pricezoo <- zoo::na.locf(pricev, na.rm=FALSE, fromLast=TRUE)
- > pricexts <- xts:::na.locf.xts(pricev, fromLast=TRUE)
- > all.equal(pricezoo, pricexts, check.attributes=FALSE)
- > library(microbenchmark)
- > summary(microbenchmark(
- + zoo=zoo::na.locf(pricev, fromLast=TRUE),
 + xts=xts:::na.locf.xts(pricev, fromLast=TRUE),
- + xts=xts:::na.loci.xts(pricev, iromLast=1kUE),
- + times=10))[, c(1, 4, 5)] # end microbenchmark summary

Coercing Time Series Objects Into zoo

The generic function as .zoo() coerces objects into zoo time series.

The function as.zoo() creates a zoo object with a numeric date-time index, with date-time encoded as a vear-fraction.

The year-fraction can be approximately converted to a Date object by first calculating the number of days since the epoch (1970), and then coercing the numeric days using as.Date().

The function date_decimal() from package *lubridate* converts numeric year-fraction dates into POSIXct objects.

The function date_decimal() provides a more accurate way of converting a year-fraction index to POSIXct.

```
> class(EuStockMarkets) # Multiple ts object
> # Coerce mts object into zoo
> zoots <- as.zoo(EuStockMarkets)
> class(zoo::index(zoots)) # Index is numeric
> head(zoots, 3)
> # Approximately convert index into class "Date"
> zoo::index(zoots) <-
    as.Date(365*(zoo::index(zoots)-1970))
> head(zoots, 3)
> # Convert index into class "POSIXct"
```

> zoo::index(zoots) <- date decimal(zoo::index(zoots))

> zoots <- as.zoo(EuStockMarkets)

> head(zoots, 3)

Coercing zoo Time Series Into Class ts

The generic function as.ts() from package stats coerces time series objects (including zoo) into ts time series.

The function as.ts() creates a ts object with a frequency=1, implying a "day" time unit, instead of a "year" time unit suitable for year-fraction dates.

A ts time series can be created from a zoo using the function ts(), after extracting the data and date attributes from zoo.

The function decimal_date() from package *lubridate* converts POSIXct objects into numeric *year-fraction* dates.

```
> set.seed(1121, "Mersenne-Twister", sample.kind="Rejection")
> # Create index of daily dates
> dates <- seq(from=as.Date("2014-07-14"), by="day", length.out=100"
> # Create vector of geometric Brownian motion
> datay <- exp(cumsum(rnorm(NROW(dates))/100))
> # Create zoo time series of geometric Brownian motion
> zoots <- zoo(x=datav, order.bv=dates)
> head(zoots, 3) # zoo object
> # as.ts() creates ts object with frequency=1
> tseries <- as.ts(zoots)
> tsp(tseries) # Frequency=1
> # Get start and end dates of zoots
> startd <- decimal date(start(zoots))
> endd <- decimal date(end(zoots))
> # Calculate frequency of zoots
> tstep <- NROW(zoots)/(endd-startd)
> datay <- zoo::coredata(zoots) # Extract data from zoots
> # Create ts object using ts()
> tseries <- ts(data=datay, start=startd, frequency=tstep)
> # Display start of time series
> window(tseries, start=start(tseries),
+ end=start(tseries)+4/365)
> head(time(tseries)) # Display index dates
```

> head(as.Date(date_decimal(zoo::coredata(time(tseries)))))

> head(tseries, 7)

Coercing Irregular Time Series Into Class ts

Irregular time series cannot be properly coerced into $\it ts$ time series without modifying their index.

The function as.ts() creates NA values when it coerces irregular time series into a ts time series.

```
> # Create weekday Boolean vector
> weekdayv <- weekdays(zoo::index(zoots))
> is_weekday <- !((weekdayv == "Saturday") |
    (weekdayv == "Sunday"))
> # Remove weekends from zoo time series
> zoots <- zoots[is_weekday, ]
> head(zoots, 7) # zoo object
> # as.ts() creates NA values
> tseries <- as.ts(zoots)
> head(tseries, 7)
> # Create vector of regular dates, including weekends
> dates <- seq(from=start(zoots),
              by="day",
              length.out=NROW(zoots))
> zoo::index(zoots) <- dates
> tseries <- as.ts(zoots)
```

> indexTZ(xtsv)

Class xts Time Series Objects

The package xts defines time series objects of class xts,

- Class xts is an extension of the zoo class (derived from zoo),
- Class xts is the most widely accepted time series class,
- Class xts is designed for high-frequency and OHLC data,
- Class xts contains many convenient functions for plotting, calculating rolling max, min, etc.

The function xts() creates a xts object from a numeric vector or matrix, and an associated date-time index.

The xts index is a vector of date-time objects, and can be from any date-time class.

The xts class can manage irregular time series whose date-time index isn't equally spaced.

```
> set.seed(1121, "Mersenne-Twister", sample.kind="Rejection")
> library(xts) # Load package xts
> # Create xts time series of random returns
> dates <- Sys.Date() + 0:3
> xtsv <- xts(rnorm(NROW(dates)), order.by=dates)
> names(xtsv) <- "random"
> xtsv
> tail(xtsv, 3) # Get last few elements
> first(xtsv) # Get first element
> last(xtsv) # Get last element
> class(xtsv) # Class "xts"
> attributes(xtsv)
# Get the time zone of an xts object
```

Coercing zoo Time Series Into Class xts

The function as.xts() coerces zoo time series into xts series.

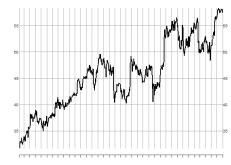

as.xts() preserves the *index* attributes of the original time series.

xts can be plotted using the generic function plot(), which dispatches the plot.xts() method.

```
> library(xts) # Load package xts
> # as.xts() coerces zoo series into xts series
> pricexts <- as.xts(pricezoo)
> dim(pricexts)
> head(pricexts[, 1:4], 4)
> # Plot using plot.xts method
> xts::plot.xts(pricexts[, "Close"], xlab="", ylab="", main="")
> title(main="MSFT prices") # Add title
```

MSFT Prices

2013-09-09 / 2016-09-0

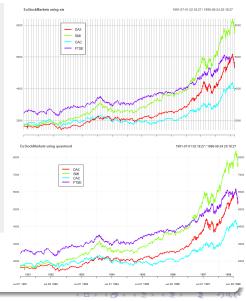

o 09 2013 Mar 03 2014 Aug 01 2014 Jan 02 2015 Jun 01 2015 Nov 02 2015 Apr 01 2016 Sep 01 201

Plotting Multiple xts Using Packages xts and quantmod

```
> library(lubridate) # Load lubridate
> # Coerce EuStockMarkets into class xts
> xtsv <- xts(zoo::coredata(EuStockMarkets),
        order.by=date_decimal(zoo::index(EuStockMarkets)))
> # Plot all columns in single panel: xts v.0.9-8
> colorv <- rainbow(NCOL(xtsv))
> plot(xtsv, main="EuStockMarkets using xts",
      col=colorv, major.ticks="years",
      minor.ticks=FALSE)
> legend("topleft", legend=colnames(EuStockMarkets),
 inset=0.2, cex=0.7, , lty=rep(1, NCOL(xtsv)),
+ lwd=3, col=colorv, bg="white")
> # Plot only first column: xts v.0.9-7
> plot(xtsv[, 1], main="EuStockMarkets using xts",
      col=colorv[1], major.ticks="years",
      minor.ticks=FALSE)
> # Plot remaining columns
> for (colnum in 2:NCOL(xtsv))
   lines(xtsv[, colnum], col=colorv[colnum])
> # Plot using quantmod
> library(quantmod)
> plot theme <- chart theme()
> plot theme$col$line.col <- colors
> chart Series(x=xtsv, theme=plot theme.
        name="EuStockMarkets using quantmod")
> legend("topleft", legend=colnames(EuStockMarkets).
+ inset=0.2, cex=0.7, , lty=rep(1, NCOL(xtsv)),
```

+ lwd=3, col=colory, bg="white")

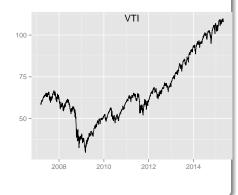

Plotting xts Using Package ggplot2

xts time series can be plotted using the package ggplot2.

The function qplot() is the simplest function in the ggplot2 package, and allows creating line and bar plots.

```
The function theme() customizes plot objects.
```

```
> library(ggplot2)
> pricev <- rutils::etfenv$prices[, 1]
> pricev <- na.omit(pricev)
> # Create ggplot object
> plotobj <- qplot(x=zoo::index(pricev),
            y=as.numeric(pricev),
            geom="line",
            main=names(pricev)) +
  xlab("") + ylab("") +
   theme( # Add legend and title
     legend.position=c(0.1, 0.5),
     plot.title=element_text(vjust=-2.0),
     plot.background=element_blank()
    ) # end theme
> # Render ggplot object
> plotobi
```

Plotting Multiple xts Using Package ggplot2

Multiple xts time series can be plotted using the function ggplot() from package ggplot2.

But ggplot2 functions don't accept time series objects, so time series must be first coerced into data frames.

```
> library(rutils) # Load xts time series data
> library(reshape2)
> library(ggplot2)
> pricev <- rutils::etfenv$prices[, c("VTI", "IEF")]
> pricev <- na.omit(pricev)
> # Create data frame of time series
> dframe <- data.frame(dates=zoo::index(pricev),
      zoo::coredata(pricev))
> # reshape data into a single column
> dframe <-
    reshape2::melt(dframe, id="dates")
> x11(width=6, height=5) # Open plot window
> # ggplot the melted dframe
> ggplot(data=dframe,
  mapping=aes(x=dates, y=value, colour=variable)) +
  geom_line() +
  xlab("") + ylab("") +
   ggtitle("VTI and IEF") +
   theme( # Add legend and title
      legend.position=c(0.2, 0.8),
      plot.title=element_text(vjust=-2.0)
```

Time series with multiple columns must be reshaped into a single column, which can be performed using the function melt() from package reshape2.

) # end theme

Interactive Time Series Plots Using Package dygraphs

The function dygraph() from package *dygraphs* creates interactive, zoomable plots from *xts* time series.

The function dyOptions() adds options (like colors, etc.) to a *dygraph* plot.

The function dyRangeSelector() adds a date range selector to the bottom of a *dygraphs* plot.

```
> # Load rutils which contains effenv dataset
> library(rutils)
> library(dygraphs)
> pricev <- rutils::etfenv$prices[, c("VTI", "IEF")]
> pricev <- na.omit(pricev)
> # Plot dygraph with date range selector
> dygraph(pricev, main="VTI and IEF prices") %>%
+ dy0tprions(colors=c("blue","green")) %>%
```

dvRangeSelector()

The *dygraphs* package in R is an interface to the *dygraphs JavaScript* charting library.

Interactive *dygraphs* plots require running *JavaScript* code, which can be embedded in *html* documents, and displayed by web browsers.

But *pdf* documents can't run *JavaScript* code, so they can't display interactive *dygraphs* plots,

Interactive Time Series Plots Using Package plotly

The function plot_lv() from package plotly creates interactive plots from data residing in data frames.

The function add_trace() adds elements to a plotly plot.

The function layout() modifies the layout of a plotly plot.

```
> # Load rutils which contains etfenv dataset
> library(rutils)
> library(plotly)
> pricev <- rutils::etfenv$prices[. c("VTI", "IEF")]
> pricev <- na.omit(pricev)
> # Create data frame of time series
> dframe <- data.frame(dates=zoo::index(pricev),
      zoo::coredata(pricev))
> # Plotly syntax using pipes
```

layout(title="VTI and IEF prices",

xaxis=list(title="Time"),

yaxis=list(title="Stock Prices"),

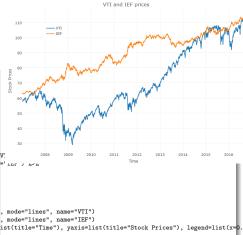

legend=list(x=0.1, y=0.9)) > # Or use standard plotly syntax

> plotobj <- plot_ly(data=dframe, x="dates, y="VTI, type="scatter", mode="lines", name="VTI") > plotobj <- add_trace(p=plotobj, x="dates, y="IEF, type="scatter", mode="lines", name="IEF")

> plotobj <- layout(p=plotobj, title="VTI and IEF prices", xaxis=list(title="Time"), yaxis=list(title="Stock Prices"), legend=list(x=0

> plotobj

> dframe %>%

Subsetting xts Time Series

xts time series can be subset in similar ways as zoo time series.

In addition, xts time series can be subset using date strings, or date range strings, for example: ["2014-10-15/2015-01-10"].

xts time series can be subset by year, week, days, or even seconds

If only the date is subset, then a comma "," after the date range isn't necessary.

The function .subset_xts() allows fast subsetting of xts time series, which for large datasets can be faster than the bracket "[]" notation.

- > # Subset xts using a date range string
- > pricev <- rutils::etfenv\$prices
- > pricesub <- pricev["2014-10-15/2015-01-10", 1:4]
- > first(pricesub)
- > last(pricesub)
- > # Subset Nov 2014 using a date string
- > pricesub <- pricev["2014-11", 1:4]
- > first(pricesub) > last(pricesub)
- > # Subset all data after Nov 2014
- > pricesub <- pricev["2014-11/", 1:4] > first(pricesub)
- > last(pricesub)
- > # Comma after date range not necessary
- > all.equal(pricev["2014-11",], pricev["2014-11"]) > # .subset_xts() is faster than the bracket []
- > library(microbenchmark)
- > summary(microbenchmark(
- bracket=pricev[10:20,],
- subset=xts::.subset_xts(pricev, 10:20),
- times=10))[, c(1, 4, 5)]

Fast Subsetting of xts Time Series

Subsetting of xts time series can be made much faster if the right operations are used.

Subsetting xts time series using Boolean vectors is usually faster than using date strings.

But the speed of subsetting can be reduced by additional operations, like coercing strings into dates.

- > # Specify string representing a date > datev <- "2014-10-15"
- > # Subset prices in two different ways
- > pricev <- rutils::etfenv\$prices
- > all.equal(pricev[zoo::index(pricev) >= datev],
 - pricev[paste0(datev, "/")])
- > # Boolean subsetting is slower because coercing string into date
- > library(microbenchmark)
- > summary(microbenchmark(
- boolean=(pricev[zoo::index(pricev) >= datev]),
- date=(pricev[paste0(datev, "/")]), times=10))[, c(1, 4, 5)] # end microbenchmark summary
- > # Coerce string into a date
- > datev <- as.Date("2014-10-15")</pre>
- > # Boolean subsetting is faster than using date string
- > summary(microbenchmark(
- boolean=(pricev[zoo::index(pricev) >= datev]),
- date=(pricev[paste0(datev, "/")]),
- times=10))[, c(1, 4, 5)] # end microbenchmark summary

Subsetting Recurring xts Time Intervals

A recurring time interval is the same time interval every day, for example the time interval from 9:30AM to 4:00PM every day.

xts series can be subset on recurring time intervals using the "T" notation.

For example, to subset the time interval from 9:30AM to 4:00PM every day: ["T09:30:00/T16:00:00"]

Warning messages that "timezone of object is different than current timezone" can be suppressed by calling the function options() with argument > pricev <- HighFreq::SPY["2012-04"]

> # Subset recurring time interval using "T notation",

> pricev <- pricev["T10:30:00/T15:00:00"]

> first(pricev["2012-04-16"]) # First element of day

> last(pricev["2012-04-16"]) # Last element of day

> # Suppress timezone warning messages

> options(xts_check_tz=FALSE)

"xts check tz=FALSE"

> all.equal(vti, vtifl)

Binding xts Time Series by Rows

The function rbind() joins the rows of xts time series.

If the time series have overlapping time indices then the join produces duplicate rows with the same dates.

The duplicate rows can be removed using the function $\operatorname{duplicated}()$.

The function duplicated() returns a Boolean vector indicating the duplicate elements of a vector.

The function duplicated() with argument "fromLast=TRUE" identifies duplicate elements starting from the end.

```
> # Create time series with overlapping time indices
> vti1 <- rutils::etfenv$VTI["/2015"]
> vti2 <- rutils::etfenv$VTI["2014/"]
> dates1 <- zoo::index(vti1)
> dates2 <- zoo::index(vti2)</pre>
> # Join by rows
> vti <- rbind(vti1, vti2)
> dates <- zoo::index(vti)
> sum(duplicated(dates))
> vti <- vti[!duplicated(dates), ]
> all.equal(vti, rutils::etfenv$VTI)
> # Alternative method - slightly slower
> vti <- rbind(vti1, vti2[!(zoo::index(vti2) %in% zoo::index(vti1))
> all.equal(vti, rutils::etfenv$VTI)
> # Remove duplicates starting from the end
> vti <- rbind(vti1, vti2)
> vti <- vti[!duplicated(dates), ]
> vtifl <- vti[!duplicated(dates, fromLast=TRUE), ]
```

Properties of xts Time Series

xts series always have a dim attribute, unlike zoo, which have no dim attribute when they only have one column of data.

zoo series with multiple columns have a ${\tt dim}$ attribute, and are therefore matrices.

But zoo with a single column don't, and are therefore vectors not matrices.

When a zoo is subset to a single column, the dim attribute is dropped, which can create errors.

```
> pricev <- rutils::etfenv$prices[, c("VTI", "IEF")]
> pricev <- na.omit(pricev)
> str(pricev) # Display structure of xts
> # Subsetting zoo to single column drops dim attribute
> pricezoo <- as.zoo(pricev)
> dim(pricezoo]
> dim(pricezoo[, 1])
> # zoo with single column are vectors not matrices
> c(is.matrix(pricezoo], is.matrix(pricezoo[, 1]))
> # xts always have a dim attribute
> rbind(base=dim(pricev), subs=dim(pricev[, 1]))
> c(is.matrix(pricev], is.matrix(pricev[, 1]))
```

lag() and diff() Operations on xts Time Series

The methods xts::lag() and xts::diff() for xts series differ from those of package zoo.

By default, the method xts::lag() replaces the current value with values from the past (negative lags replace with values from the future).

The methods zoo::lag() and zoo::diff() shorten the series by the number of lag periods.

By default, the methods xts::lag() and xts::diff() retain the same number of elements, by padding with leading or trailing NA values.

In order to avoid padding with NA values, asset returns can be padded with zeros, and prices can be padded with the first or last elements of the input vector.

- > # Lag of zoo shortens it by one row
- > rbind(base=dim(pricezoo), lag=dim(lag(pricezoo)))
- > # Lag of xts doesn't shorten it
- > rbind(base=dim(pricev), lag=dim(lag(pricev)))
- > # Lag of zoo is in opposite direction from xts
- > head(lag(pricezoo, -1), 4)
- > head(lag(pricev), 4)

Determining Calendar End points of xts Time Series

The function endpoints() from package xts extracts the indices of the last observations in each calendar period of time of an xts series.

For example:

endpoints(x, on="hours")

extracts the indices of the last observations in each hour.

The end points calculated by endpoints() aren't always equally spaced, and aren't the same as those calculated from fixed intervals.

For example, the last observations in each day aren't equally spaced due to weekends and holidays.

- > # Indices of last observations in each hour
- > endd <- xts::endpoints(pricev, on="hours")
- > head(endd)
- > # Extract the last observations in each hour
- > head(pricev[endd,])

Converting xts Time Series to Lower Periodicity

The function to.period() converts a time series to a lower periodicity (for example from hourly to daily periodicity).

to.period() returns a time series of open, high, low, and close values (OHLC) for the lower period.

to.period() converts both univariate and *OHLC* time series to a lower periodicity.

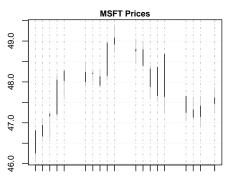

- > # Lower the periodicity to months
- > pricem <- to.period(x=pricev, period="months", name="MSFT")
- > # Convert colnames to standard OHLC format
- > colnames(pricem)
- > colnames(pricem) <- sapply(
- + strsplit(colnames(pricem), split=".", fixed=TRUE),
- + function(na_me) na_me[-1]
 +) # end sapply
- +) # end sapply > head(pricem, 3)
- > # Lower the periodicity to years
- > pricesy <- to.period(x=pricem, period="years", name="MSFT")
- > colnames(pricevy) <- sapply(
- strsplit(colnames(pricevy), split=".", fixed=TRUE),
- + function(na_me) na_me[-1]
- +) # end sapply > head(pricevy)

Plotting OHLC Time Series Using plot.xts()

The method (function) plot.xts() can plot OHLC time series of class xts.

```
> pricexts <- as.xts(pricezoo)
> # Subset xts using a date
> pricexts <- pricexts["2014-11", 1:4]
> # Plot OHLC using plot.xts method
> xts::plot.xts(pricexts, type="candles", main="")
> title(main="MSFT Prices") # Add title
```

> library(xts) # Load package xts > # as.xts() coerces zoo series into xts series

Nov 03 2014 Nov 11 2014 Nov 19 2014 Nov 28 2014

Time Series Classes in R

R and other packages contain a number of different time series classes:

- Class ts from base package stats: native time series class in R, but allows only regular (equally spaced) date-time index, not suitable for sophisticated financial applications,
- Class zoo: allows irregular date-time index, the zoo index can be from any date-time class,
- Class xts extension of zoo class: most widely accepted time series class, designed for high-frequency and OHLC data, contains convenient functions for plotting, calculating rolling max, min, etc.
- Class timeSeries from the Rmetrics suite.

- > pricev <- as.ts(pricezoo)
- > class(pricev)
 > tail(pricev[, 1:4])
- > library(xts) > pricexts <- as.xts(pricezoo)
- > pricexts <- as.xts(pricezoo)
- > class(pricexts)
- > tail(pricexts[, 1:4])

Writing Text Strings

The function cat() concatenates strings and writes them to standard output or to files.

cat() parses its argument character string and its escape sequences ("\"), but doesn't return a value.

The function print() doesn't interpret its argument, and simply prints it to standard output and invisibly returns it.

Typing the name of an object in R implicitly calls print() on that object.

The function save() writes objects to compressed binary .RData files.

```
> cat("Enter\ttab") # Cat() parses backslash escape sequences
> print("Enter\ttab")
>
> textv <- print("hello")
> textv # Print() returns its argument
>
> # Create string
> textv <- "Title: My Text\nSome numbers: 1,2,3,...\nRprofile files
> cat(textv, file="mytext.txt") # Write to text file
> cat("Title: My Text", # Write several lines to text file
+ "Some numbers: 1,2,3,...",
+ "Rprofile files contain code executed at R startup,",
+ file="mytext.txt", sep="\n")
> save(textv, file="mytext.RData") # Write to binary file
```

Displaying Numeric Data

The function print() displays numeric data objects, with the number of digits given by the global option "digits".

The function sprintf() returns strings formatted from text strings and numeric data.

```
> print(pi)
[1] 3.14
> print(pi, digits=10)
[1] 3.141592654
> getOption("digits")
[1] 3
> foo < 12
> bar <= "weeks"
> sprintf("There are %i %s in the year", foo, bar)
[1] "There are 12 weeks in the year"
```

Reading Text from Files

The function scan() reads text or data from a file and returns it as a vector or a list.

The function readLines() reads lines of text from a connection (file or console), and returns them as a vector of character strings.

The function readline() reads a single line from the console, and returns it as a character string.

The function file.show() reads text or data from a file and displays in editor.

```
> # Read text from file
> scan(file="mytext.txt", what=character(), sep="\n")
> # Read lines from file
> readlines(con="mytext.txt")
> # Sead text from console
> input <- readline("Enter a number: ")
> class(input)
> # Coerce to numeric
> input <- as.numeric(input)
> # Sead text from file and display in editor:
> # file.show("mytext.txt")
> # file.show("mytext.txt")
> # file.show("mytext.txt", pager="")
```

Writing and Reading Data Frames from Text Files

The functions write.table() and read.table() write and read $\it data\ frames$ from text files.

write.table() coerces objects to data frames before
it writes them.
read.table() returns a data frame, without coercing

non-numeric values to factors (so no need for the option stringsAsFactors=FALSE).

write.table() and read.table() can be used to write and read matrices from text files, but they have to be coerced back to matrices.

write.table() and read.table() are inefficient for very large data sets.

```
> setwd("/Users/jerzy/Develop/lecture_slides/data")
> dframe <- data.frame(type=c("rose", "daisy", "tulip"),
+ color=c("red", "white", "yellow"),
   price=c(1.5, 0.5, 1.0),
   row.names=c("flower1", "flower2", "flower3")) # end data.frame
> matv <- matrix(sample(1:12), ncol=3,
   dimnames=list(NULL, c("col1", "col2", "col3")))
> rownames(matv) <- paste("row", 1:NROW(matv), sep="")
> # Write data frame to text file, and then read it back
> write.table(dframe, file="florist.txt")
> readf <- read.table(file="florist.txt")
> readf # A data frame
> all.equal(readf, dframe)
> # Write matrix to text file, and then read it back
> write.table(matv. file="matrix.txt")
> readmat <- read.table(file="matrix.txt")
> readmat # write.table() coerced matrix to data frame
> class(readmat)
> all.equal(readmat, matv)
> # Coerce from data frame back to matrix
> readmat <- as.matrix(readmat)
> class(readmat)
```

> all.equal(readmat, matv)

Copying Data Frames Between the clipboard and R

Data frames stored in the clipboard can be copied into R using the function read.table().

Data frames in R can be copied into the clipboard using the function write.table().

This allows convenient copying of $\it data\ frames$ between R and Excel.

Data frames can also be manipulated directly in the R spreadsheet-style data editor.

Copying and pasting between the ${\it clipboard}$ and R works well on Windows, but not on MacOS. There are some workarounds for MacOS:

Copy_paste_between_R_and_clipboard

```
> # Create a data frame
> dframe <- data.frame(small=c(3, 5), medium=c(9, 11), large=c(15,
> # Launch spreadsheet-style data editor
> dframe <- edit(dframe)
> # Copy the data frame to clipboard
> write.table(x=dframe, file="clipboard", sep="\t")
> # Wrapper function for copying data frame from R into clipboard
> # by default, data is tab delimited, with a header
> write_clip <- function(data, row.names=FALSE, col.names=TRUE,
   write.table(x=data, file="clipboard", sep="\t",
        row.names=row.names, col.names=col.names, ...)
+ } # end write_clip
> write_clip(data=dframe)
> # Wrapper function for copying data frame from clipboard into R
> # by default, data is tab delimited, with a header
> read_clip <- function(file="clipboard", sep="\t", header=TRUE,
   read.table(file=file, sep=sep, header=header, ...)
+ } # end read clip
> dframe <- read.table("clipboard", header=TRUE)
> dframe <- read clip()
```

Writing and Reading Data Frames From .csv Files

The easiest way to share data between R and Excel is through .csv files.

The functions write.csv() and read.csv() write and read data frames from .csv format files.

The functions write.csv() and read.csv() write and read data frames from .csv format files.

These functions are *wrappers* for write.table() and read.table().

read.csv() doesn't coerce non-numeric values to
factors, so no need for the option
stringsAsFactors=FALSE.

read.csv() reads row names as an extra column, unless the row.names=1 argument is used.

The argument "row.names" accepts either the number or the name of the column containing the row names.

The *.csv() functions are very inefficient for large data sets.

- > # Write data frame to CSV file, and then read it back
 > write.csv(dframe, file="florist.csv")
- > readf <- read.csv(file="florist.csv")
- > readf # the row names are read in as extra column
- > # Restore row names
- > rownames(readf) <- readf[, 1]
- > readf <- readf[, -1] # Remove extra column
- > readf
- > all.equal(readf, dframe)
- > # Read data frame, with row names from first column
- > readf <- read.csv(file="florist.csv", row.names=1)
- > readf
- > all.equal(readf, dframe)

Writing and Reading Data Frames From .csv Files (cont.)

The functions write.csv() and read.csv() can write and read data frames from .csv format files without using row names.

Row names can be omitted from the output file by calling write.csv() with the argument row names=FALSE.

- > # Write data frame to CSV file, without row names
 > write.csv(dframe, row.names=FALSE, file="florist.csv")
- > readf <- read.csv(file="florist.csv")
- > readf # A data frame without row names
- > all.equal(readf, dframe)

Jerzy Pawlowski (NYU Tandon)

Reading Data From Very Large .csv Files

Data from very large .csv files can be read in small chunks instead of all at once.

The function file() opens a connection to a file or an internet website URI.

The function read.csv() with the argument "nrows" reads only the specified number of rows from a connection and returns a data frame. The connection pointer is reset to the next row.

The function read.csv() with the argument "nrows" allows reading data sequentially from very large files that wouldn't fit into memory.

- > # Open a read connection to a file > con_read = file("/Users/jerzy/Develop/lecture_slides/data/etf_pri
- > # Read the first 10 rows
- > data10 <- read.csv(con_read, nrows=10)
- > # Read another 10 rows
- > data20 <- read.csv(con_read, nrows=10, header=FALSE)
- > colnames(data20) <- colnames(data10) > # Close the connection to the file
- > close(con read)
- > # Open a read connection to a file
- > con_read = file("/Users/jerzy/Develop/lecture_slides/data/etf_pri > # Read the first 1000 rows
- > data10 <- read.csv(con_read, nrows=1e3)
- > colnamev <- colnames(data10)
 - > # Write to a file
- > county <- 1
- > write.csv(data10, paste0("/Users/jerzy/Develop/data/temp/etf_price
 - > # Read remaining rows in a loop 10 rows at a time > # Can produce error without getting to end of file
- > while (isOpen(con_read)) {
- datay <- read.csv(con read. nrows=1e3)
- colnames(datav) <- colnamev
- write.csv(datav, paste0("/Users/jerzy/Develop/data/temp/etf_pri county <- county + 1
- + } # end while

Writing and Reading Matrices From .csv Files

The functions write.csv() and read.csv() can write and read matrices from .csv format files.

If row names can be omitted in the output file, then write.csv() can be called with argument row.names=FALSE.

If the input file doesn't contain row names, then read.csv() can be called without the "row.names" argument.

- > # Write matrix to csv file, and then read it back > write.csv(matv, file="matrix.csv")
- > readmat <- read.csv(file="matrix.csv", row.names=1)
- > readmat # Read.csv() reads matrix as data frame
- > class(readmat)
 > readmat <- as.matrix(readmat) # Coerce to matrix</pre>
- > all.equal(readmat, matv)
- > write.csv(matv, row.names=FALSE,
 + file="matrix_ex_rows.csv")
- > readmat <- read.csv(file="matrix_ex_rows.csv")
 - > readmat <- as.matrix(readmat)
- > readmat # A matrix without row names
- > all.equal(readmat, matv)

Writing and Reading Matrices (cont.)

There are several ways of writing and reading matrices from .csv files, with tradeoffs between simplicity, data size, and speed.

The function write.matrix() writes a matrix to a text file, without its row names.

write.matrix() is part of package MASS.

The advantage of function scan() is its speed, but it doesn't handle row names easily.

Removing row names simplifies the writing and reading of matrices.

The function readLines reads whole lines and returns them as single strings.

```
> setwd("/Users/jerzy/Develop/lecture_slides/data")
> library(MASS) # Load package "MASS"
> # Write to CSV file by row - it's very SLOW!!!
> MASS::write.matrix(matv, file="matrix.csv", sep=",")
> # Read using scan() and skip first line with colnames
> readmat <- scan(file="matrix.csv", sep=",", skip=1,
    what=numeric())
> # Read colnames
> colnamev <- readLines(con="matrix.csv", n=1)
> colnamev # this is a string!
> # Convert to char vector
> colnamev <- strsplit(colnamev, split=".")[[1]]
> readmat # readmat is a vector, not matrix!
> # Coerce by row to matrix
> readmat <- matrix(readmat, ncol=NROW(colnamev), byrow=TRUE)
> # Restore colnames
> colnames(readmat) <- colnamev
> readmat
> # Scan() is a little faster than read.csv()
> library(microbenchmark)
> summary(microbenchmark(
    read csv=read.csv("matrix.csv").
    scan=scan(file="matrix.csv", sep=",",
      skip=1, what=numeric()),
    times=10))[, c(1, 4, 5)] # end microbenchmark summary
```

Reading Matrices Containing Bad Data

Very often data that is read from external sources contains elements with bad data. An example of bad data are character strings within

sets of numeric data Columns of numeric data that contain strings are coerced to character or factor, when they're read by read.csv()

The function as.numeric() coerces complex data objects into numeric vectors, and removes all their attributes

as.numeric() coerces strings that don't represent numbers into NA values.

- > # Read data from a csv file, including row names
- > matv <- read.csv(file="matrix_bad.csv", row.names=1)
- > matv > class(matv)
- > # Columns with bad data are character or factor
- > sapply(matv, class)
- > # Coerce character column to numeric
- > maty\$col2 <- as.numeric(maty\$col2) > # Or
 - > # Copy row names
 - > rownames <- row.names(matv)
 - > # sapply loop over columns and coerce to numeric
- > matv <- sapply(matv, as.numeric)
- > # Restore row names
- > row.names(matv) <- rownames
- > # Replace NAs with zero > matv[is.na(matv)] <- 0
- > # matrix without NAs
- > matv

Writing and Reading Time Series From *Text* Files

The package zoo contains functions write.zoo() and read.zoo() for writing and reading zoo time series from .txt and .csv files.

The functions write.zoo() and read.zoo() are wrappers for write.table() and read.table().

The function write, zoo() writes the zoo series index as a character string in quotations "", to make it easier to read (parse) by read.zoo().

Users may also directly use write.table() and read.table(), instead of write.zoo() and read.zoo().

```
> library(zoo) # Load package zoo
> # Create zoo with Date index
> dates <- seg(from=as.Date("2013-06-15"), by="day",
          length.out=100)
> pricev <- zoo(rnorm(NROW(dates)), order.bv=dates)
> head(pricev. 3)
> # Write zoo series to text file, and then read it back
> write.zoo(pricev, file="pricev.txt")
> pricezoo <- read.zoo("pricev.txt") # Read it back
> all.equal(pricezoo, pricev)
> # Perform the same using write.table() and read.table()
> # First coerce pricev into data frame
> dframe <- as.data.frame(pricev)
> dframe <- cbind(dates, dframe)
> # Write pricev to text file using write.table
> write.table(dframe, file="pricev.txt",
        row.names=FALSE, col.names=FALSE)
> # Read data frame from file
> pricezoo <- read.table(file="pricev.txt")
> sapply(pricezoo, class) # A data frame
> # Coerce data frame into pricev
> pricezoo <- zoo::zoo(
    drop(as.matrix(pricezoo[, -1])).
    order.by=as.Date(pricezoo[, 1]))
> all.equal(pricezoo, pricev)
```

Writing and Reading Time Series From .csv Files

By default the functions zoo::write.zoo() and zoo::read.zoo() write data in space-delimited text format, but they can also write to comma-delimited .csv files by passing the parameter sep=",".

Single column zoo time series usually don't have a dimension attribute, and they don't have a column name, unlike multi-column zoo time series, and this can cause hard to detect bugs.

It's best to always pass the argument "col.names=TRUE" to the function write.zoo(), to make sure it writes a column name for a single column zoo time series.

Reading a .csv file containing a single column of data using the function read.zoo() produces a zoo time series with a NULL dimension, unless the argument "drop=FALSE" is passed to read.zoo().

Users may also directly use write.table() and read.table(), instead of write.zoo() and read.zoo().

- > # Write zoo series to CSV file, and then read it back
- > write.zoo(pricev, file="pricev.csv", sep=",", col.names=TRUE)
 > pricezoo <- read.zoo(file="pricev.csv",</pre>
- + header=TRUE, sep=",", drop=FALSE)
- > all.equal(pricev, drop(pricezoo))

Writing and Reading Time Series With Date-time Index

The function read.csv.zoo() reads zoo time series from .csv files.

The function xts::as.xts() coerces zoo time series into xts series

If the index of a zoo time series is a date-time, then write.zoo() writes the date and time fields as character strings separated by a space between them. inside quotations "".

Very often .csv files contain custom date-time formats, which need to be passed as parameters into read.zoo() for proper formatting.

The "FUN" argument of read.zoo() accepts a function for coercing the date and time columns of the input data into a date-time object suitable for the zoo index.

The function as .POSIXct() coerces character strings into POSIXct date-time objects.

```
> set.seed(1121, "Mersenne-Twister", sample.kind="Rejection")
> # Create zoo with POSTXct date-time index
```

> dates <- seq(from=as.POSIXct("2013-06-15"),

by="hour", length.out=100) > pricev <- zoo(rnorm(NROW(dates)), order.bv=dates)

> head(pricev. 3)

> # Write zoo series to CSV file, and then read it back

> write.zoo(pricev, file="pricev.csv", sep=",", col.names=TRUE)

> # Read from CSV file using read.csv.zoo() > pricezoo <- read.csv.zoo(file="pricev.csv")

> all.equal(pricev. pricezoo)

> # Coerce to xts series

> xtsv <- xts::as.xts(pricezoo) > class(xtsv): head(xtsv, 3)

> # Coerce zoo series into data frame with custom date format > dframe <- as.data.frame(pricev)

> dframe <- cbind(format(dates, "%m-%d-%Y %H:%M:%S"), dframe)

> head(dframe, 3) > # Write zoo series to csv file using write.table

> write.table(dframe, file="pricev.csv",

sep=",", row.names=FALSE, col.names=FALSE) > # Read from CSV file using read.csv.zoo()

> pricezoo <- read.zoo(file="pricev.csv".

header=FALSE, sep=",", FUN=as.POSIXct,

format="%m-%d-%Y %H:%M:%S", tz="America/New_York")

> # Or using read.csv.zoo()

> pricezoo <- read.csv.zoo(file="pricev.csv", header=FALSE,

+ format="%m-%d-%Y %H:%M:%S", tz="America/New_York") > head(pricezoo, 3)

> all.equal(pricev, pricezoo)

Reading Time Series With Numeric Date-time Index

If the index of a time series is numeric (representing the moment of time, either as the number of days or seconds), then it must be coerced to a proper date-time class.

A convenient way of reading time series with a numeric index is by using read.table(), and then coercing the data frame into a time series.

The function as.POSIXct.numeric() coerces a numeric value representing the moment of time into a POSIXct date-time, equal to the clock time in the local time zone.

```
> # Read time series from CSV file, with numeric date-time
> datazoo <- read.table(file="/Users/jerzy/Develop/lecture_slides/d
+ header=FNUE, sep=",")
> # A data frame
> class(datazoo)
> sapply(datazoo, class)
> # Coerce data frame into xts series
> datazoo <- xts::xts(as.matrix(datazoo[, -i]),
+ order.by=as.POSIXct.numeric(datazoo[, 1], tz="America/New_York"
+ origin="1970-01-01"))
> # An xts series
> class(datazoo)
> head(datazoo, 3)
```

> save(list=ls()[1], file="my_data.RData")
> # Save whole list by passing it to the "list" argument

> save(list=ls(), file="my_data.RData")

Passing Arguments to the save() Function

The function save() writes objects to a binary file.

Object names can be passed into save() either through the "..." argument, or the "list" argument.

Objects passed through the "..." argument are not evaluated, so they must be either object names or character strings.

Object names aren't surrounded by quotes "", while character strings that represent object names are surrounded by quotes "".

Objects passed through the "list" argument are evaluated, so they may be variables containing character strings.

```
> var1 <- 1; var2 <- 2
> ls()  # List all objects
> ls()[1] # List first object
> args(save) # List arguments of save function
> # Save "var1" to a binary file using string argument
> save("var1", file="my_data.RData")
> # Save "var1" to a binary file using object name
> save(var1, file="my_data.RData")
> # Save multiple objects
> save(var1, var2, file="my_data.RData")
> # Save first object in list by passing to "..." argument
> # ls()[1] is not evaluated
> save(ls()[1], file="my_data.RData")
> # Save first object in list by passing to "list" argument
```

Writing and Reading Lists of Objects

The function load() reads data from .RData files, and invisibly returns a vector of names of objects created in the workspace.

The vector of names can be used to manipulate the objects in loops, or to pass them to functions.

```
> rm(list=ls()) # Remove all objects
> # Load objects from file
> loadobj <- load(file="my_data.RData")
> loadob; # vector of loaded objects
> ls() # List objects
> # Assign new values to objects in global environment
> sapply(loadobj, function(symbol) {
   assign(symbol, runif(1), envir=globalenv())
+ }) # end sapply
> ls() # List objects
> # Assign new values to objects using for loop
> for (symbol in loadobi) {
   assign(symbol, runif(1))
+ } # end for
> ls() # List objects
> # Save vector of objects
> save(list=loadobj, file="my_data.RData")
> # Remove only loaded objects
> rm(list=loadobi)
> # Remove the object "loadobi"
> rm(loadobi)
```

Saving Output of R to a File

The function sink() diverts R text output (excluding graphics) to a file, or ends the diversion.

Remember to call sink() to end the diversion!

The function pdf() diverts graphics output to a pdf file (text output isn't diverted), in vector graphics format.

The functions png(), jpeg(), bmp(), and tiff() divert graphics output to graphics files (text output isn't diverted).

The function dev.off() ends the diversion.

```
> sink("sinkdata.txt")# Redirect text output to file
> cat("Redirect text output from R\n")
> print(runif(10))
> cat("\nEnd data\nbve\n")
> sink() # turn redirect off
> pdf("Rgraph.pdf", width=7, height=4) # Redirect graphics to pdf
> cat("Redirect data from R into pdf file\n")
> myvar <- seq(-2*pi, 2*pi, len=100)
> plot(x=myvar, y=sin(myvar), main="Sine wave",
     xlab="", vlab="", type="1", lwd=2, col="red")
> cat("\nEnd data\nbve\n")
> dev.off() # turn pdf output off
> png("r_plot.png") # Redirect graphics output to png file
> cat("Redirect graphics from R into png file\n")
> plot(x=myvar, y=sin(myvar), main="Sine wave",
+ xlab="", vlab="", type="1", lwd=2, col="red")
> cat("\nEnd data\nbye\n")
> dev.off() # turn png output off
```

Package data.table for High Performance Data Management

The package *data.table* is designed for high performance data management.

The package *data.table* implements *data table* objects, which are a special type of *data frame*, and an extension of the *data frame* class.

Data tables are faster and more convenient to work with than data frames.

data.table functions are optimized for high performance (speed), because they are written in C++ and they perform operations by reference (in place), without copying data in memory.

Some of the attractive features of package *data.table* are:

- Syntax is analogous to SQL,
- Very fast writing and reading from files,
- Very fast sorting and merging operations,
- Subsetting using multiple logical clauses,
- Columns of type character are never converted to factors,

- > # Install package data.table
- > install.packages("data.table")
- > # Load package data.table
 > library(data.table)
- > # Get documentation for package data.table
- > # Get short description
- > packageDescription("data.table")
- > # Load help page
- > help(package="data.table")
- > # List all datasets in "data.table"
- > data(package="data.table")
- > # List all objects in "data.table"
- > ls("package:data.table")
 > # Remove data.table from search path
- > detach("package:data.table")

The package *data.table* has extensive documentation:

https://cran.r-project.org/web/packages/data.table/ vignettes/datatable-intro.html

https://github.com/Rdatatable/data.table/wiki

rcode=NROW(dtable).

Data Table Objects

Data table objects are a special type of data frame, and are derived from the class data.frame.

Data table objects resemble databases, with columns of different types of data, and rows of records containing individual observations.

The function data.table::data.table() creates a data table object.

Data table columns can be referenced directly by their names (without quotes), and their rows can be referenced without a following comma.

When a data table is printed (by typing its name) then only the top 5 and bottom 5 rows are displayed (unless getOption("datatable.print.nrows") is less than 1001.

The operator $.\mathbb{N}$ returns the number of observations (rows) in the $data\ table$.

Data table computations are usually much faster than equivalent R computations, but not always.

```
> # Create a data table
> library(data.table)
> dtable <- data.table::data.table(</pre>
    col1=sample(7), col2=sample(7), col3=sample(7))
> # Print dtable
> class(dtable): dtable
> # Column referenced without quotes
> dtable[, col2]
> # Row referenced without a following comma
> dtable[2]
> # Print option "datatable.print.nrows"
> getOption("datatable.print.nrows")
> options(datatable.print.nrows=10)
> getOption("datatable.print.nrows")
> # Number of rows in dtable
> NROW(dtable)
> # Nr
> dtable[, NROW(col1)]
> # Nr
> dtable[, .N]
> # microbenchmark speed of data.table syntax
> library(microbenchmark)
> summary(microbenchmark(
    dt=dtable[. .N].
```

times=10))[, c(1, 4, 5)] # end microbenchmark summary

Writing and Reading Data Using Package data.table

The easiest way to share data between R and Excel is through .csv files.

The function data.table::fread() reads from .csv files and returns a data table object of class data.table

Data table objects are a special type of data frame, and are derived from the class data, frame

The function data.table::fread() is over 6 times faster than read.csv()!

The function data.table::fwrite() writes to .csv files over 12 times faster than the function write.csv(), and 300 times faster than function cat()!

- > # Read a data table from CSV file
- > dir_name <- "/Users/jerzy/Develop/lecture_slides/data/"
- > file_name <- file.path(dir_name, "weather_delays14.csv")
- > dtable <- data.table::fread(file name) > class(dtable): dim(dtable)
- > dtable
- > # fread() reads the same data as read.csv()
- > all.equal(read.csv(file_name),
- setDF(data.table::fread(file name))) > # fread() is much faster than read.csv()
- > library(microbenchmark)
- > summary(microbenchmark(
- rcode=read.csv(file_name),
- fread=setDF(data.table::fread(file_name)),
- times=10))[, c(1, 4, 5)] # end microbenchmark summary
- > # Write data table to file in different ways
- > data.table::fwrite(dtable, file="dtable.csv")
- > write.csv(dtable, file="dtable2.csv")
- > cat(unlist(dtable), file="dtable3.csv")
- > # microbenchmark speed of data.table::fwrite()
- > summary(microbenchmark(
- fwrite=data.table::fwrite(dtable, file="dtable.csv"),
- write csv=write.csv(dtable, file="dtable2.csv").
- cat=cat(unlist(dtable), file="dtable3.csv"),
- times=10))[, c(1, 4, 5)] # end microbenchmark summary

Subsetting Data Table Objects

The square braces (brackets) "[]" operator subsets (references) the rows and columns of *data tables*.

Data table rows can be subset without a following comma.

Data table columns can be referenced directly by their names (without quotes, as if they were variables), after a comma.

Multiple data table columns can be referenced by passing a list of names.

The brackets "[]" operator is a *data.table* function, and all the commands inside the brackets "[]" are executed using code from the package *data.table*.

The dot .() operator is equivalent to the list function list().

- > # Select first five rows of dtable
 > dtable[1:5]
- > # Select rows with JFK flights
- > jfk_flights <- dtable[origin=="JFK"]
- > # Select rows JFK flights in June
- > jfk_flights <- dtable[origin=="JFK" & month==6]
- > # Select rows without JFK flights
- > jfk_flights <- dtable[!(origin=="JFK")]
 > # Select flights with carrier_delay
- > dtable[carrier_delay > 0]
- > # Select column of dtable and return a vector
- > # Select column of dtable and lettin a vecto
- > head(dtable[, origin])
- > # Select column of dtable and return a dtable, not vector
- > head(dtable[, list(origin)])
- > head(dtable[, .(origin)])
- > # Select two columns of dtable
- > dtable[, list(origin, month)]
 > dtable[, .(origin, month)]
- > columnv <- c("origin", "month")
- > dtable[, ..columnv]
- > dtable[, month, origin]
- > # Select two columns and rename them > dtable[, .(orig=origin, mon=month)]
- > # Select all columns except origin
- > head(dtable[, !"origin"])
- > head(dtable[, !"origin"])
 > head(dtable[, -"origin"])
- > head(dtable[, -"origin"])

Performing Computations on Data Table Columns

If the second argument in the brackets "[]" operator is a function of the columns, then the brackets return the result of the function's computations on those columns.

The second argument in the brackets "[]" can also be a list of functions, in which case the brackets return a vector of computations.

The brackets "[]" can evaluate most standard $\tt R$ functions, but they are executed using ${\it data.table}$ code, which is usually much faster than the equivalent $\tt R$ functions.

The operator .N returns the number of observations (rows) in the *data table*.

```
> # Select flights with positive carrier delay
> dtable[carrier_delay > 0]
> # Number of flights with carrier_delay
> dtable[, sum(carrier_delay > 0)]
> # Or standard R commands
> sum(dtable[, carrier_delay > 0])
> # microbenchmark speed of data.table syntax
> summary(microbenchmark(
    dt=dtable[, sum(carrier_delay > 0)],
    rcode=sum(dtable[, carrier_delay > 0]),
    times=10))[, c(1, 4, 5)] # end microbenchmark summary
> # Average carrier_delay
> dtable[, mean(carrier_delay)]
> # Average carrier_delay and aircraft_delay
> dtable[, .(carrier=mean(carrier_delay),
       aircraft=mean(aircraft_delay))]
> # Average aircraft_delay from JFK
> dtable[origin=="JFK", mean(aircraft_delay)]
> # Number of flights from JFK
> dtable[origin=="JFK", NROW(aircraft_delay)]
> dtable[origin=="JFK", .N]
```

> # In R

> sum(dtable[, origin] == "JFK")

Grouping Data Table Computations by Factor Columns

The $data\ table$ brackets "[]" operator can accept three arguments: [i, j, by]

- i: the row index to select,
- j: a list of columns or functions on columns,
- by: the columns of factors to aggregate over.

The data table columns can be aggregated over categories (factors) defined by one or more columns passed to the "by" argument.

The "keyby" argument is similar to "by", but it sorts the output according to the categories used to group by. Multiple *data table* columns can be referenced by passing a list of names.

The dot .() operator is equivalent to the list function list().

- > # Number of flights from each airport
- > dtable[, .N, by=origin]
 > # Same, but add names to output
- > dtable[, .(flights=.N), by=.(airport=origin)]
- > # Number of AA flights from each airport
- > dtable[carrier=="AA", .(flights=.N), by=.(airport=origin)]
- > # Number of flights from each airport and airline
- \rightarrow dtable[, .(flights=.N), by=.(airport=origin, airline=carrier)]
- > # Average aircraft_delay
- > dtable[, mean(aircraft_delay)]
- > # Average aircraft_delay from JFK
- > dtable[origin=="JFK", mean(aircraft_delay)]
- > # Average aircraft_delay from each airport
- > dtable[, .(delay=mean(aircraft_delay)), by=.(airport=origin)]
- > # Average and max delays from each airport and month
- > dtable[, .(mean_delay=mean(aircraft_delay), max_delay=max(aircraft_delay)
- + by=.(airport=origin, month=month)]
- > # Average and max delays from each airport and month
- > dtable[, .(mean_delay=mean(aircraft_delay), max_delay=max(aircraf
 + keyby=.(airport=origin, month=month)]

4 D > 4 P > 4 E > 4 E > E 9 Q C

Sorting Data Table Rows by Columns

Standard R functions can be used inside the brackets "[]" operator.

The function order() calculates the permutation index, to sort a given vector into ascending order.

The function setorder() sorts the rows of a *data table* by reference (in place), without copying data in memory.

setorder() is over 10 times faster than order(),
because it doesn't copy data in memory.

Several brackets "[]" operators can be chained together to perform several consecutive computations.

- > # Sort ascending by origin, then descending by dest
- > dtables <- dtable[order(origin, -dest)]
- > dtables
- > # Doesn't work outside dtable
- > order(origin, -dest)
- > # Sort dtable by reference
- > setorder(dtable, origin, -dest)
 > all.equal(dtable, dtables)
- > # setorder() is much faster than order()
- > summary(microbenchmark(
- + order=dtable[order(origin, -dest)],
- + setorder=setorder(dtable, origin, -dest),
- + times=10))[, c(1, 4, 5)] # end microbenchmark summary
 > # Average aircraft_delay by month
- > dtables[, .(mean_delay=mean(aircraft_delay)),
- + by=.(month=month)]
- > # Chained brackets to sort output by month
- > dtables[, .(mean_delay=mean(aircraft_delay)),
- + by=.(month=month)][order(month)]

Subsetting, Computing, and Grouping Data Table Objects

The special symbol .SD selects a subset of a *data table*.

Inside the brackets "[]" operator, the .SD symbol can be treated as a virtual *data table*, and standard R functions can be applied to it.

The "by" argument can be used to group the outputs produced by the functions applied to the .SD symbol.

If the symbol .SDcols is not defined, then the symbol .SD returns the remaining columns not passed to the "by" operator.

```
> # Select weather delay and aircraft delay in two different ways
> dtable[1:7, .SD,
       .SDcols=c("weather_delay", "aircraft_delay")]
> dtable[1:7, .(weather_delay, aircraft_delay)]
> # Calculate mean of weather_delay and aircraft_delay
> dtable[, sapply(.SD, mean),
       .SDcols=c("weather_delay", "aircraft_delay")]
> sapply(dtable[, .SD,
       .SDcols=c("weather_delay", "aircraft_delay")], mean)
> # Return origin and dest, then all other columns
> dtable[1:7, .SD, by=.(origin, dest)]
> # Return origin and dest, then weather_delay and aircraft_delay c
> dtable[1:7, .SD, by=.(origin, dest),
       .SDcols=c("weather_delay", "aircraft_delay")]
> # Return first two rows from each month
> dtable[, head(.SD, 2), by=.(month)]
> dtable[, head(.SD, 2), by=.(month),
       .SDcols=c("weather_delay", "aircraft_delay")]
> # Calculate mean of weather_delay and aircraft_delay, grouped by
> dtable[, lapply(.SD, mean),
       by=.(origin).
       .SDcols=c("weather delay", "aircraft delay")]
> # Or simply
> dtable[, .(weather_delay=mean(weather_delay),
```

aircraft_delay=mean(aircraft_delay)),

by=.(origin)]

Modifying Data Table Objects by Reference

The special assignment operator ":=" allows modifying data table columns by reference (in place), without copying data in memory.

The computations on columns by reference can be *grouped* over categories defined by one or more columns passed to the "by" argument.

The computations are recycled to fit the size of each group.

The selected parts of columns can also be modified by reference, by combining the ${\tt i}$ and ${\tt j}$ arguments.

The special symbols .SD and .SDcols can be used to perform computations on several columns.

Modifying by reference is several times faster than standard R assignment.

```
> # Add tot delay column
> dtable[, tot_delay := (carrier_delay + aircraft_delay)]
> head(dtable, 4)
> # Delete tot_delay column
> dtable[, tot_delay := NULL]
> # Add max_delay column grouped by origin and dest
> dtable[, max_delay := max(aircraft_delay), by=.(origin, dest)]
> dtable[, max_delay := NULL]
> # Add date and tot_delay columns
> dtable[, c("date", "tot_delay") :=
         list(paste(month, day, year, sep="/"),
              (carrier_delay + aircraft_delay))]
> # Modify select rows of tot_delay column
> dtable[month == 12, tot_delay := carrier_delay]
> dtable[, c("date", "tot_delay") := NULL]
> # Add several columns
> dtable[, c("max_carrier", "max_aircraft") := lapply(.SD, max),
+ by=.(origin, dest),
+ .SDcols=c("carrier_delay", "aircraft_delay")]
> # Remove columns
> dtable[, c("max carrier", "max aircraft") := NULL]
> # Modifying by reference is much faster than standard R
> summary(microbenchmark(
    dt=dtable[, tot delay := (carrier delay + aircraft delay)].
    rcode=(dtable[, "tot_delay"] <- dtable[, "carrier_delay"] + dta
```

times=10))[, c(1, 4, 5)] # end microbenchmark summary

> summary(microbenchmark(

with kev=dtable[.("JFK", "MIA")].

Adding keys to Data Tables for Fast Binary Search

The *key* of a *data table* is analogous to the row indices of a *data frame*, and it determines the ordering of its rows.

The function data.table::setkey() adds a key to a data table, and sorts the data table rows by reference according to the key.

setkey() creates the *key* from one or more columns of the *data frame*.

Subsetting rows using a *key* can be several times faster than standard R.

```
> # Add a key based on the "origin" column
> setkey(dtable, origin)
> haskey(dtable)
> key(dtable)
> # Select rows with LGA using the key
> dtable["LGA"]
> all.equal(dtable["LGA"], dtable[origin == "LGA"])
> # Select rows with LGA and JFK using the key
> dtable[c("LGA", "JFK")]
> # Add a key based on the "origin" and "dest" columns
> setkey(dtable, origin, dest)
> key(dtable)
> # Select rows with origin from JFK and MIA
> dtable[c("JFK", "MIA")]
> # Select rows with origin from JFK and dest to MIA
> dtable[.("JFK", "MIA")]
> all.equal(dtable[.("JFK", "MIA")],
      dtable[origin == "JFK" & dest == "MIA"])
> # Selecting rows using a key is much faster than standard R
```

standard_r=dtable[origin == "JFK" & dest == "MIA"],
times=10))[, c(1, 4, 5)] # end microbenchmark summary

Coercing Data Table Objects Into Data Frames

The functions data.table::setDT() and data.table::setDF() coerce data frames to data tables, and vice versa.

The set functions data.table::set*() perform their operations by reference (in place), without returning any values or copying data to a new memory location, which makes them very fast.

Data table objects can also be coerced into data frames using the function as.data.frame(), but it's much slower because it makes copies of data.

- > # Create data frame and coerce it to data table
- > dtable <- data.frame(col1=sample(7), col2=sample(7), col3=sample(
- > class(dtable); dtable
 > data.table::setDT(dtable)
- > class(dtable); dtable
- > # Coerce dtable into data frame
- > data.table::setDF(dtable)
 > class(dtable); dtable
- > # Or
- > dtable <- data.table:::as.data.frame.data.table(dtable)
- > # SetDF() is much faster than as.data.frame()
- > summary(microbenchmark(
- + asdataframe=data.table:::as.data.frame.data.table(dtable),
- + setDF=data.table::setDF(dtable),
- + times=10))[, c(1, 4, 5)] # end microbenchmark summary

Coercing xts Time Series Into Data Tables

An xts time series can be coerced into a data table by first coercing it into a data frame and then into a data table using the function data.table::setDT().

But then the time index of the xt.s series is coerced into strings, not dates.

An xts time series can also be coerced directly into a data table using the function data.table::as.data.table().

- > # Coerce xts to a data frame > pricev <- rutils::etfenv\$VTI
- > class(pricev); head(pricev) > pricev <- as.data.frame(pricev)
- > class(pricev); head(pricev)
- > # Coerce data frame to a data table
- > data.table::setDT(pricev, keep.rownames=TRUE)
- > class(pricev); head(pricev)
- > # Dates are coerced to strings
- > sapply(pricev, class)
- > # Coerce xts directly to a data table
- > dtable <- as.data.table(rutils::etfenv\$VTI,
- keep.rownames=TRUE)
- > class(dtable); head(dtable)
- > # Dates are not coerced to strings
- > sapply(dtable, class)
- > all.equal(pricev, dtable, check.attributes=FALSE)

Package fst for High Performance Data Management

The package *fst* provides functions for very fast writing and reading of *data frames* from *compressed binary files*.

The package fst writes to compressed binary files in the fst fast-storage format.

The package *fst* uses the LZ4 and ZSTD compression algorithms, and utilizes multithreaded (parallel) processing on multiple CPU cores.

The package *fst* has extensive documentation: http://www.fstpackage.org/

```
> # Install package fst

> install.packages("fst")

> # Load package fst

> library(fst)

> # Get documentation for package fst

> # Get short description

> packageDescription("fst")

> # Load help page

> help(package="fst")

> # List all datasets in "fst"

> data(package="fst")

> # List all datasets in "fst"
```

> ls("package:fst")
> # Remove fst from search path

> detach("package:fst")

81 / 113

Writing and Reading Data Using Package fst

The package *fst* allows very fast writing and reading of *data frames* from *compressed binary files* in the fst fast-storage format.

The function fst::write_fst() writes to .fst files over 10 times faster than the function write.csv(), and 300 times faster than function cat() write to .csv files!

The function fst::fread() reads from .fst files over 10 times faster than the function read.csv() from .csv files!

- > # Read a data frame from CSV file
- > dir_name <- "/Users/jerzy/Develop/lecture_slides/data/"
 > file_name <- file.path(dir_name, "weather_delays14.csv")</pre>
- > file_name <- file.path(dir_name, "weather_delays14.csv
 > data.table::setDF(dframe)
- > class(dframe): dim(dframe)
- > # Write data frame to .fst file in different ways
- > fst::write_fst(dframe, path="dframe.fst")
- > write.csv(dframe, file="dframe2.csv")
- > # microbenchmark speed of fst::write_fst()
- > library(microbenchmark)
 > summary(microbenchmark(
- + fst=fst::write_fst(dframe, path="dframe.csv"),
- + write_csv=write.csv(dframe, file="dframe2.csv"),
- + cat=cat(unlist(dframe), file="dframe3.csv"),
 + times=10))[, c(1, 4, 5)] # end microbenchmark summary
- > # fst::read fst() reads the same data as read.csv()
- > # ist::read_ist() reads the same data as read.csv(
 > all.equal(read.csv(file_name),
- all.equal(read.csv(lile_name),
- fst::read_fst("dframe.fst"))
- > # fst::read_fst() is 10 times faster than read.csv()
- > summary(microbenchmark(
- + fst=fst::read_fst("dframe.fst"),
- + read_csv=read.csv(file_name),
- + times=10))[, c(1, 4, 5)] # end microbenchmark summary

> class(refst)

> dim(taq); dim(refst)
> fst:::print.fst table(refst)

> refst[1e4:(1e4+5),]

Random Access to Large Data Files

The package fst allows random access to very large data frames stored in compressed data files in the .fst format.

Data frames can be accessed *randomly* by loading only the selected rows and columns into memory, without fully loading the whole data frame.

function fst::fst() reads an .fst file and returns an fst.table reference object (pointer) to the data, without loading the whole data into memory.

The fst_table reference provides access to the data similar to a regular data frame, but it requires only a small amount of memory because the data isn't loaded into memory.

```
> # Coerce TAQ xts to a data frame
> library(HighFreq)
> taq < HighFreq::SPY_TAQ
> taq < as. data.frame(taq)
> class(taq)
> # Coerce data frame to a data table
> data.table::setDT(taq, keep.rownames=TRUE)
> class(taq); head(taq)
> # Get memory size of data table
> format(object.size(taq), units="MB")
> # Save data table to .fst file
> fst::write_fst(taq, path="/Users/jerzy/Develop/data/taq.fst")
> # Create reference to .fst file similar to a data frame
> refst <- fst::fst("Users/jerzy/Develop/data/taq.fst")</pre>
```

> # Reference to .fst can be treated similar to a data table

> # Memory size of reference to .fst is very small
> format(object.size(refst), units="MB")

> # Subset reference to .fst just like a data table

> # Get sizes of all objects in workspace

> sort(sapply(mget(ls()), object.size))

Downloading ts Time Series Using tseries

in ts format using the argument "retclass="ts".

get.hist.quote() returns a ts object with a
frequency=1, implying a "day" time unit, instead of a
"year" time unit suitable for year-fraction dates.

get.hist.quote() can download daily historical data

The ts contains NA values for weekends and holidays.

```
> library(tseries) # Load package tseries
> # Download MSFT data in ts format
> pricemsft <- suppressWarnings(
    get.hist.quote(
      instrument="MSFT".
      start=Svs.Date()-3*365.
      end=Svs.Date().
      retclass="ts".
      quote=c("Open", "High", "Low", "Close",
        "AdjClose", "Volume"),
      origin="1970-01-01")
     # end suppressWarnings
> # Calculate price adjustment vector
> ratio <- as.numeric(pricemsft[, "AdjClose"]/pricemsft[, "Close"])
> # Adjust OHLC prices
> pricemsftadi <- pricemsft
> pricemsftadj[, c("Open", "High", "Low", "Close")] <-
    ratio*pricemsft[, c("Open", "High", "Low", "Close")]
> # Inspect the data
> tsp(pricemsftadj) # frequency=1
> head(time(pricemsftadj))
> head(pricemsftadj)
> tail(pricemsftadj)
```

Downloading zoo Time Series Using tseries

The function get.hist.quote() downloads historical data from online sources.

The "provider" argument determines the *online* source, and its default value is c("yahoo", "oanda").

The "retclass" argument determines the return class, and its default value is c("zoo", "its", "ts").

The "quote" argument determines the data fields, and its default value is c("Open", "High", "Low", "Close").

The "AdjClose" data field is for the *Close* price adjusted for stock splits and dividends.

- > # Download MSFT data
- > pricezoo <- suppressWarnings(
- + get.hist.quote(
 + instrument="MSFT",
- + start=Sys.Date()-3*365,
- end=Sys.Date(),
- quote=c("Open","High","Low","Close",
- "AdjClose", "Volume"), origin="1970-01-01")
- +) # end suppressWarnings
- > class(pricezoo) > dim(pricezoo)
- > head(pricezoo, 4)

Adjusting OHLC Data

Stock prices experience jumps due to stock splits and dividends.

 $\ensuremath{\textit{Adjusted}}$ stock prices are stock prices that have been adjusted so they don't have jumps.

 $\ensuremath{\textit{OHLC}}$ data can be adjusted for stock splits and dividends.

- > # Calculate price adjustment vector
- > ratio <- as.numeric(pricezoo[, "AdjClose"]/pricezoo[, "Close"])
- > head(ratio, 5) > tail(ratio, 5)
- > # Adjust OHLC prices
- > # Adjust UHLC prices
- > pricedj <- pricezoo
- > pricedj[, c("Open","High","Low","Close")] <-
- + ratio*pricezoo[, c("Open","High","Low","Close")]
 > head(pricedj)
- > tail(pricedj)

Downloading Data From Oanda Using tseries

Oanda is a foreign exchange broker that also provides free historical currency rates data.

The function get.hist.quote() downloads historical data from online sources.

The "provider" argument determines the *online* source, and its default value is c("yahoo", "oanda").

The "retclass" argument determines the return class, and its default value is c("zoo", "its", "ts").

The "quote" argument determines the data fields, and its default value is c("Open", "High", "Low", "Close").

The function complete.cases() returns TRUE if a row has no NA values.

```
> # Download EUR/USD data
> priceur <- suppressWarnings(
    get.hist.quote(
      instrument="EUR/USD".
      provider="oanda".
      start=Sys.Date()-3*365,
      end=Svs.Date().
      origin="1970-01-01")
    # end suppressWarnings
> # Bind and scrub data
> pricecombo <- cbind(priceur, pricezoo[, "AdiClose"])
> colnames(pricecombo) <- c("EURUSD", "MSFT")
> pricecombo <- pricecombo[complete.cases(pricecombo),]
> save(pricezoo, pricedi.
       pricemsft, pricemsftadj,
       priceur, pricecombo.
       file="/Users/jerzy/Develop/lecture_slides/data/zoo_data.RDat
> # Inspect the data
> class(priceur)
```

> head(priceur, 4)

Downloading Stock Prices Using tseries

Data for multiple symbols can be downloaded in an lapply() loop, which calls the function tseries::get.hist.quote.

If the body of an apply() loop returns a zoo or xts series, then the loop will produce an error, because apply() attempts to coerce its output into a vector or matrix.

So lapply() should be used instead of apply().

The functional lapply() applies a function to a list of objects and returns a list of objects.

The list of zoo time series can be flattened into a single zoo series using functions do.call() and cbind().

The function do.call() executes a function call using a function name and a list of arguments.

The function do_call() from package *rutils* performs the same operation as do.call(), but using recursion, which is much faster and uses less memory.

paste, c("Close", "Volume"), sep="."))

> # Save pricev to a comma-separated CSV file

> save(pricev, file="pricev.RData")

> write.zoo(pricev, file="pricev.csv", sep=",")
> # Save pricev to a binary .RData file

Reading Data From Excel Files

The package *readxl* reads data from Excel spreadsheet files into R.

The function read_excel() reads a single sheet (tab) from an Excel file.

The function read_xlsx() reads a single sheet (tab) from an Excel file in .xlsx format.

The functions from package *readxl* return a type of *data frame* called a *tibble* object.

The *tibble* classes tbl and tbl_df are derived from the data frame class data.frame.

tibble objects are also used by the package dplyr.

DataCamp offers a Tutorial on Importing Excel Files into R.

```
> # Install and load package readxl
> install.packages("readxl")
> library(readx1)
> dir_name <- "/Users/jerzy/Develop/lecture_slides/data"
> filev <- file.path(dir_name, "multi_tabs.xlsx")
> # Read a time series from first sheet of xlsx file
> tibblev <- readxl::read_xlsx(filev)
> class(tibblev)
> # Coerce POSIXct dates into Date class
> class(tibblev$Dates)
> tibblev$Dates <- as.Date(tibblev$Dates)
> # Some columns are character strings
> sapply(tibblev, class)
> sapply(tibblev, is.character)
> # Coerce columns with strings to numeric
> listv <- lapply(tibblev, function(x) {
    if (is.character(x))
      as.numeric(x)
    else
+ }) # end lapply
> # Coerce list into xts time series
> xtsv <- xts::xts(do.call(cbind, listv)[, -1], listv[[1]])
> class(xtsv): dim(xtsv)
> # Replace NA values with the most recent non-NA values
> sum(is.na(xtsv))
> xtsv <- zoo::na.locf(xtsv, na.rm=FALSE)
> xtsv <- zoo::na.locf(xtsv, fromLast=TRUE)
```

Reading Multiple Sheets From Excel Files

The function readxl::excel_sheets() returns a vector of character strings with the names of all the sheets in an Excel spreadsheet.

The package readxI reads data from Excel spreadsheet files into R.

The function read_excel() reads a single sheet (tab) from an Excel file.

The function read_xlsx() reads a single sheet (tab) from an Excel file in .xlsx format.

The functions from package *readxl* return a type of *data frame* called a *tibble* object.

The tibble classes tbl and tbl_df are derived from the data frame class data.frame.

tibble objects are also used by the package dplyr.

```
> # Read names of all the sheets in an Excel spreadsheet
> namev <- readxl::excel_sheets(filev)
> # Read all the sheets from an Excel spreadsheet
> sheets <- lapply(namev, read_xlsx, path=filev)
> names(sheets) <- namev
> # sheets is a list of tibbles
> sapply(sheets, class)
> # Create function to coerce tibble to xts
> to_xts <- function(tibblev) {
    tibblev$Dates <- as.Date(tibblev$Dates)
    # Coerce columns with strings to numeric
    listv <- lapply(tibblev, function(x) {
      if (is.character(x))
        as.numeric(x)
      else
        х
    }) # end lapply
    # Coerce list into xts series
    xts::xts(do.call(cbind, listv)[, -1], listv$Dates)
+ } # end to xts
> # Coerce list of tibbles to list of xts
> class(sheets)
> sheets <- lapply(sheets, to xts)
> sapply(sheets, class)
> # Replace NA values with the most recent non-NA values
> sapply(sheets, function(xtsv) sum(is.na(xtsv)))
> sheets <- lapply(sheets, zoo::na.locf, na.rm=FALSE)
> sheets <- lapply(sheets, zoo::na.locf, fromLast=TRUE)
```

Performing Calculations in Excel Using R

Excel can run R using either VBA scripts, or through a COM interface (available on Windows only).

R can perform calculations and export its output to Excel files, or it can modify Excel files (requires packages using Java or Perl code).

Calculations in ${\tt R}$ and ${\tt Excel}$ can be combined in several different ways:

- Data from Excel can be exchanged with R via .csv files (simplest and best method),
- Excel can execute R commands using VBA scripts, and then import the R output from .csv files,
- An Excel add-in can execute R commands as Excel functions (relies on COM protocol, so works only for Windows): add-ins BERT, RExcel,
- R can modify Excel files and run Excel functions (requires packages using Java or Perl code): packages xlsx, XLConnect, excel.link,

```
> ### Perform calculations in R,
> ### And export to CSV files
> setwd("/Users/jerzy/Develop/lecture_slides/data")
> # Read data frame, with row names from first column
> readf <- read.csy(file="florist.csy", row.names=1)
> # Subset data frame
> readf <- readf[readf[, "type"]=="daisy", ]
> all.equal(readf, dframe)
> # Write data frame to CSV file, with row names
> write.csy(readf, file="daisis.csy")
```

Running R Code from Excel

There are several ways of performing calculations in R and exporting the outputs to Excel:

- Export data from Excel via .csv files to R, perform the calculations in R, and import the outputs back to Excel via .csv files (simplest and best method),
- Run R from Excel using VBA scripts, and exchange data via .csv files,
- Run R from Excel using an Excel add-in, and execute R commands as Excel functions (relies on the COM protocol, so works only for Windows),

```
> ### Perform calculations in R,
> ### And export to CSV files
> setud("/Users/jerzy/Develop/lecture_slides/data")
> # Read data frame, with row names from first column
> readf <- read.csv(file="florist.csv", row.names=1)
> # Subset data frame
> readf(readf, "type"]=="daisy", ]
> all.equal(readf, dframe)
> # Write data frame to CSV file, with row names
```

> write.csv(readf, file="daisies.csv")

92 / 113

Running R Code Using VBA Scripts

An R session can be launched from Excel using a VBA script (macro).

The VBA function shell() executes a program by running an executable *exe* file (with extension *exe*).

A VBA script can also run an R batch process.

The R batch process can write to .csv files, which can then be imported into Excel.

' VBA macro to run R process
Sub run_r()
Call shell("R", vbNormalFocus)

/ VBA macro to run interactive R process
Sub run_rinteractive()

Dim script_dir As String: script_dir = "C:\Develop\R\script
Dim script_file As String: script_file = "plot_interactiv

BERT Excel Add-in for Running R Code

BERT is an Excel add-in which allows executing R commands as Excel functions:

http://bert-toolkit.com/ http://bert-toolkit.com/bert-quick-start

https://github.com/sdllc/Basic-Excel-R-Toolkit/wikihttps://github.com/sdllc/Basic-Excel-R-Toolkit

BERT launches its own R process from Excel.

BERT can create its own menu in the Excel add-ins tab:

After installing BERT, click on upper-left Office Button, click Excel options, on the bottom of the window choose (Manage: COM Add-ins) Go, add the COM add-in BERTRibbon2x86.dll.

BERT relies on the COM protocol, so it works only for Windows.

' calculate sum of Excel cells using R R.Add(B1:D1)

' remove NAs over Excel cell range using R function R.na_omit(F2:H4)

' calculate eigenValues of Excel matrix using R function R.EigenValues(A1:H8)

> # Install latest version of googlesheets

> gs_read_csv(google_sheet, ws=tab_s[1])

> google_sheet %>% gs_read(ws=tab_s[1])

> # Download data from sheet into file
> gs_download(google_sheet, ws=tab_s[1],

> # Open sheet in internet browser > gs browse(google sheet)

> # Or using dplyr pipes

Package googlesheets for Interacting with Google Sheets

The package *googlesheets* allows interacting with *Google Sheets* using R commands.

If you already have a *Google* account, then your personal *Google Sheets* can be found at:

https://docs.google.com/spreadsheets/

The function gs_ls() listv the files in Google Sheets.

The function gs_title() registers a *Google* sheet, and returns a googlesheet object.

A googlesheet object contains information (metadata) about a *Google* sheet, such as its name and key, but not the sheet data itself.

The function gs_browse() opens a *Google* sheet in an internet browser.

You can find online a document about using googlesheets.

You can find online a document about managing authentication tokens.

```
> devtools::install_github("jennybc/googlesheets")
> # Load package googlesheets
> library(googlesheets)
> library(dplyr)
> # Authenticate authorize R to view and manage your files
> gs_auth(new_user=TRUE)
> # List the files in Google Sheets
> googlesheets::gs_ls()
> # Register a sheet
> google_sheet <- gs_title("my_data")
> # view sheet summary
> google_sheet
> # List tab names in sheet
> tab_s <- gs_ws_ls(google_sheet)
> # Set curl options
> library(httr)
> httr::set_config(config(ssl_verifypeer=OL))
> # Read data from sheet
> gs_read(google_sheet)
> # Read data from single tab of sheet
> gs_read(google_sheet, ws=tab_s[1])
```

to="/Users/jerzy/Develop/lecture_slides/data/google_sheet.c

Package Rcpp for Calling C++ Programs from R

The package Rcpp allows calling C++ functions from R. by compiling the C++ code and creating R functions.

Rcpp functions are R functions that were compiled from C++ code using package Rcpp.

Rcpp functions are much faster than code written in R. so they're suitable for large numerical calculations.

The package Rcpp relies on Rtools for compiling the C++ code.

https://cran.r-project.org/bin/windows/Rtools/

You can learn more about the package Rcpp here:

http://adv-r.had.co.nz/Rcpp.html

http://www.rcpp.org/

http://gallerv.rcpp.org/

Function cppFunction() for Compiling C++ code

The function cppFunction() compiles C++ code into an R. function.

The function cppFunction() creates an R function only for the current R session, and it must be recompiled for every new R session.

The function sourceCpp() compiles C++ code contained in a file into R functions

- > # Define Rcpp function
- > Rcpp::cppFunction(" int times_two(int x)
 - { return 2 * x;}
- ") # end cppFunction
- > # Run Rcpp function
- > times_two(3)
- > # Source Rcpp functions from file
- > Rcpp::sourceCpp(file="/Users/jerzy/Develop/lecture_slides/scripts
- > # Multiply two numbers
- > mult_rcpp(2, 3) > mult_rcpp(1:3, 6:4)
- > # Multiply two vectors
- > mult_vec_rcpp(2, 3)
- > mult_vec_rcpp(1:3, 6:4)

Performing Loops in Rcpp Sugar

Loops written in Rcpp can be two orders of magnitude faster than loops in R!

 $Rcpp\ Sugar\ allows\ using\ R-style\ vectorized\ syntax\ in\ Rcpp\ code.$

> # Define Rcpp function with loop

```
> Rcpp::cppFunction("
+ double inner_mult(NumericVector x, NumericVector y) {
+ int xsize = x.size():
+ int ysize = y.size();
+ if (xsize != ysize) {
      return 0:
  } else {
      double total = 0:
     for(int i = 0: i < xsize: ++i) {
+ total += x[i] * v[i]:
   return total:
+ }") # end cppFunction
> # Run Rcpp function
> inner mult(1:3, 6:4)
> inner mult(1:3, 6:3)
> # Define Rcpp Sugar function with loop
> Rcpp::cppFunction("
+ double inner_sugar(NumericVector x, NumericVector y) {
+ return sum(x * y);
+ }") # end cppFunction
> # Run Rcpp Sugar function
> inner_sugar(1:3, 6:4)
> inner_sugar(1:3, 6:3)
```

```
> # Define R function with loop
> inner_multr <- function(x, y) {
      sumv <- 0
      for(i in 1:NROW(x)) {
+ sumv <- sumv + x[i] * v[i]
      sumv
     # end inner_multr
> # Run R function
> inner_multr(1:3, 6:4)
> inner_multr(1:3, 6:3)
> # Compare speed of Rcpp and R
> library(microbenchmark)
> summary(microbenchmark(
    rcode=inner_multr(1:10000, 1:10000),
    innerp=1:10000 %*% 1:10000,
    Rcpp=inner_mult(1:10000, 1:10000),
    sugar=inner_sugar(1:10000, 1:10000),
    times=10))[, c(1, 4, 5)]
```

} // end for

// rescale output vector and return it

return acos(1-2*output)/pi;

// Rcpp header with information for C++ compiler

draft: Rcpp Examples

```

pricev[i] <- pricev[i-1] + retp[i]

} # end for

pricev

+ } # end bootd

Simulating Ornstein-Uhlenbeck Process Using Rcpp

Simulating the Ornstein-Uhlenbeck Process in Rcpp is about 30 times faster than in R!

```
> # Define Ornstein-Uhlenbeck function in R
> sim_our <- function(nrows=1000, eq_price=5.0,
               volat=0.01, theta=0.01) {
  retp <- numeric(nrows)
   pricev <- numeric(nrows)
 pricev[1] <- eq_price
  for (i in 2:nrows) {
     retp[i] <- theta*(eq_price - pricev[i-1]) + volat*rnorm(1)
     pricev[i] <- pricev[i-1] + retp[i]
   } # end for
   pricev
+ } # end sim our
> # Simulate Ornstein-Uhlenbeck process in R
> eq_price <- 5.0; sigmav <- 0.01
> thetav <- 0.01; nrows <- 1000
> set.seed(1121, "Mersenne-Twister", sample.kind="Rejection") # Re
> ousim <- sim_our(nrows, eq_price=eq_price, volat=sigmav, theta=tl
```

```
> # Define Ornstein-Uhlenbeck function in Rcpp
> Rcpp::cppFunction("
+ NumericVector sim_oucpp(double eq_price,
                    double volat,
                    double thetav,
                    NumericVector innov) {
    int nrows = innov.size();
   NumericVector pricev(nrows);
   NumericVector retv(nrows);
   pricev[0] = eq_price;
   for (int it = 1; it < nrows; it++) {
     retv[it] = thetav*(eq_price - pricev[it-1]) + volat*innov[it-
     pricev[it] = pricev[it-1] + retv[it];
  } // end for
   return pricev;
+ }") # end cppFunction
> # Simulate Ornstein-Uhlenbeck process in Rcpp
> set.seed(1121, "Mersenne-Twister", sample.kind="Rejection") # Re
> oucpp <- sim_oucpp(eq_price=eq_price,
   volat=sigmav, theta=thetav, innov=rnorm(nrows))
> all.equal(ousim, oucpp)
> # Compare speed of Rcpp and R
> library(microbenchmark)
> summary(microbenchmark(
   rcode=sim_our(nrows, eq_price=eq_price, volat=sigmav, theta=the
   Rcpp=sim_oucpp(eq_price=eq_price, volat=sigmav, theta=thetav, i
   times=10))[, c(1, 4, 5)]
```

Rcpp Attributes

Rcpp attributes are instructions for the C++ compiler, embedded in the Rcpp code as C++ comments, and preceded by the "//" symbol.

The Rcpp::depends attribute specifies additional C++ library dependencies.

The Rcpp::export attribute specifies that a function should be exported to R, where it can be called as an R function.

Only functions which are preceded by the Rcpp::export attribute are exported to R.

The function sourceCpp() compiles C++ code contained in a file into R functions.

```
> # Source Rcpp function for Ornstein-Uhlenbeck process from file return pricev;
    Rcpp::sourceCpp(file="/Users/jerzy/Develop/lecture_slides/scripts/) // end sim_ouc
    # Simulate Ornstein-Uhlenbeck process in Rcpp
    set.seed(1121, "Mersenne-Twister", sample.kind="Rejection") # Reset random numbers
    oucpp <- sim_oucpp(eq_price=eq_price,
        volat=sigmav,
        theta=thetav,
        innov=rnorm(nrows)
    all.equal(ousim, oucpp)
    # Compare speed of Rcpp and R
    library(microbenchmark)
    summary(microbenchmark)
    * rcode=sim_our(nrows, eq_price=eq_price, volat=sigmav, theta=thetav),
    * Rcpp=sim_oucp(eq_price=eq_price, volat=sigmav, theta=thetav),
    times=100)[, c(1, 4, 5)]
```

```
// Rcpp header with information for C++ compiler
#include <Rcpp.h> // include Rcpp C++ header files
using namespace Rcpp; // use Rcpp C++ namespace
// The function sim_oucpp() simulates an Ornstein-Uhlenb
// export the function roll_maxmin() to R
// [[Rcpp::export]]
NumericVector sim_oucpp(double eq_price,
                          double volat.
                          double thetay.
                          NumericVector innov) {
  int(nrows = innov.size():
  NumericVector pricev*nrows):
  NumericVector retp*nrows);
  pricev[0] = eq_price;
  for (int it = 1: it < nrows: it++) {
    retp[it] = thetav*(eq_price - pricev[it-1]) + volat*
    pricev[it] = pricev[it-1] + retp[it];
  } // end for
  return pricev:
   // end sim oucpp
```

Generating Random Numbers Using Logistic Map in Rcpp

The logistic map in Rcpp is about seven times faster than the loop in R, and even slightly faster than the standard runif() function in R!

```
> # Calculate uniformly distributed pseudo-random sequence
> unifun <- function(seedv, nrows=10) {
   output <- numeric(nrows)
   output[1] <- seedv
 for (i in 2:nrows) {
     output[i] <- 4*output[i-1]*(1-output[i-1])
  } # end for
   acos(1-2*output)/pi
+ } # end unifun
> # Source Rcpp functions from file
> Rcpp::sourceCpp(file="/Users/jerzy/Develop/lecture_slides/scripts,// [[Rcpp::export]]
> # Microbenchmark Rcpp code
> library(microbenchmark)
> summary(microbenchmark(
   rcode=runif(1e5).
  rloop=unifun(0.3, 1e5).
+ Rcpp=unifuncpp(0.3, 1e5),
 times=10))[, c(1, 4, 5)]
```

```
// Rcpp header with information for C++ compiler
#include <Rcpp.h> // include Rcpp C++ header files
using namespace Rcpp; // use Rcpp C++ namespace
// This is a simple example of exporting a C++ function
// You can source this function into an R session using
// function Rcpp::sourceCpp()
// (or via the Source button on the editor toolbar).

draft: Converting Functions and Objects Between C++ and R

FRE6871 Lecture#7

```
C++ functions and objects need to be converted to R objects, and vice versa.

The function Rcpp::wrap() converts C++ functions and
```

objects to R objects.

The syntax as<T>() converts R objects to C++ objects.

Adapt from:

```
Rcpp-modules.pdf
https://gallery.rcpp.org/articles/custom-templated-
```

wrap-and-as-for-seamingless-interfaces/ http://dirk.eddelbuettel.com/code/rcpp.html

Simulating the Ornstein-Uhlenbeck Process in *Rcpp* is

about 30 times faster than in R!

```
> # Define Ornstein-Uhlenbeck function in R
> bootd <- function(datav, nboot=1000) {
   bootd <- sapply(1:nboot, function(x) {
      samplev <- datav[sample.int(nrows, replace=TRUE)]
      c(sd=sd(samplev), mad=mad(samplev))
  }) # end sapply
   bootd <- t(bootd)
   # Analyze bootstrapped variance
   head(bootd)
   sum(is.na(bootd))
   # Means and standard errors from bootstrap
    apply(bootd, MARGIN=2.
    function(x) c(mean=mean(x), stderror=sd(x)))
   retp <- numeric(nrows)
   pricev <- numeric(nrows)
   pricev[1] <- eg price
```

```
// Rcpp header with information for C++ compiler
#include <Rcpp.h> // include Rcpp C++ header files
using namespace Rcpp; // use Rcpp C++ namespace
// This is a simple example of exporting a C++ function
// You can source this function into an R session using
// function Rcpp::sourceCpp()
// (or via the Source button on the editor toolbar).
// Learn more about Rcpp at:

     http://adv-r.had.co.nz/Rcpp.html
     http://gallery.rcpp.org/
// function unifun() produces a vector of
// uniformly distributed pseudo-random numbers
// [[Rcpp::export]]
NumericVector unifuncpp(double seedv, int(nrows) {
// define pi
static const double pi = 3.14159265;
// allocate output vector
  NumericVector output(nrows):
// initialize output vector
  output[0] = seedv;
// perform loop
  for (int i=1: i < nrows: ++i) {
    output[i] = 4*output[i-1]*(1-output[i-1]);
  } // end for
// rescale output vector and return it
 return acos(1-2*output)/pi;
```

for (i in 2:nrows) {

Package RcppArmadillo for Fast Linear Algebra

The package RcppArmadillo allows calling from R the high-level Armadillo C++ linear algebra library.

Armadillo provides ease of use and speed, with syntax similar to Matlah

RcppArmadillo functions are often faster than even compiled R functions, because they use better optimized C++ code:

http://arma.sourceforge.net/speed.html

You can learn more about RcppArmadillo:

http://arma.sourceforge.net/ http://dirk.eddelbuettel.com/code/rcpp.armadillo.html https://cran.r-project.org/web/packages/ \emph{RcppArmadillo}/index.html

https://github.com/RcppCore/\emph{RcppArmadillo}

```
> library(RcppArmadillo)
```

- > # Source Rcpp functions from file
- > Rcpp::sourceCpp(file="/Users/jerzy/Develop/lecture_slides/script:
- > vec1 <- runif(1e5)
- > vec2 <- runif(1e5)
- > inner vec(vec1, vec2)
- > vec1 %*% vec2

```
// Rcpp header with information for C++ compiler
#include <RcppArmadillo.h>
using namespace Rcpp;
using namespace arma;
// [[Rcpp::depends(RcppArmadillo)]]
// The function inner_vec() calculates the inner (dot)
// It uses \emph{RcppArmadillo}.
//' @export
// [[Rcpp::export]]
double inner vec(arma::vec vec1, arma::vec vec2) {
  return arma::dot(vec1, vec2):
} // end inner vec
// The function inner mat() calculates the inner (dot) r
// with two vectors.
// It accepts pointers to the matrix and vectors, and re
// It uses \emph{RcppArmadillo}.
//' @export
// [[Rcpp::export]]
double inner mat(const arma::vec& vecv2. const arma::mat
  return arma::as scalar(trans(vecv2) * (matv * vecv1)):
} // end inner mat
> # Microbenchmark \emph{RcppArmadillo} code
> summary(microbenchmark(
   rcpp = inner vec(vec1, vec2).
 rcode = (vec1 %*% vec2).
   times=100))[, c(1, 4, 5)] # end microbenchmark summary
> # Microbenchmark shows:
> # inner vec() is several times faster than %*%. especially for lo
               mean median
> # 1 inner vec 110.7067 110.4530
> # 2 rcode 585 5127 591 3575
```

Simulating ARIMA Processes Using RcppArmadillo

ARIMA processes can be simulated using RcppArmadillo even faster than by using the function filter().

> # Source Rcpp functions from file

```
> Rcpp::sourceCpp(file="/Users/jerzy/Develop/lecture_slides/scripts/
> # Define AR(2) coefficients
> coeff <- c(0.9, 0.09)
> nrows <- 1e4
> set.seed(1121, "Mersenne-Twister", sample.kind="Rejection")
> innov <- rnorm(nrows)
> # Simulate ARIMA using filter()
> arimar <- filter(x=innov, filter=coeff, method="recursive")
> # Simulate ARIMA using sim ar()
> innov <- matrix(innov)
> coeff <- matrix(coeff)
> arimav <- sim ar(coeff, innov)
> all.equal(drop(arimav), as.numeric(arimar))
> # Microbenchmark \emph{RcppArmadillo} code
> summary(microbenchmark(
  rcpp = sim ar(coeff, innov).
```

+ filter = filter(x=innov, filter=coeff, method="recursive").

+ times=100))[, c(1, 4, 5)] # end microbenchmark summary

```
// Rcpp header with information for C++ compiler
#include <RcvpArmadillo.h> // include C++ header file
using namespace arma; // use C++ namespace from Armadill
// declare dependency on RcppArmadillo
// [[Rcpp::depends(RcppArmadillo)]]
//' @export
// [[Rcpp::export]]
arma::vec sim ar(const arma::vec& innov. const arma::vec
  uword nrows = innov.n elem:
  uword look back = coeff.n elem:
  arma::vec arimav[nrows]:
 // startup period
  arimav(0) = innov(0):
  arimav(1) = innov(1) + coeff(look back-1) * arimav(0):
 for (uword it = 2: it < look back-1: it++) {
    arimav(it) = innov(it) + arma::dot(coeff.subvec(look
  } // end for
  // remaining periods
  for (uword it = look_back; it < nrows; it++) {
    arimav(it) = innov(it) + arma::dot(coeff, arimav.sub
  } // end for
  return arimav;
} // end sim_arima
```

Fast Matrix Algebra Using RcppArmadillo

```
RcppArmadillo functions can be made even faster by
                                                             // Rcpp header with information for C++ compiler
                                                             #include <RcppArmadillo.h> // include C++ header file fr
operating on pointers to matrices and performing
                                                             using namespace arma; // use C++ namespace from Armadill
calculations in place, without copying large matrices.
                                                             // declare dependency on RcppArmadillo
                                                             // [[Rcpp::depends(RcppArmadillo)]]
RcppArmadillo functions can be compiled using the
same Rtools as those for Rcpp functions:
                                                             // Examples of \emph{RcppArmadillo} functions below
  https://cran.r-project.org/bin/windows/Rtools/
                                                             // The function demeanr() calculates a matrix with cente
                                                             // It accepts a pointer to a matrix and operates on the
> library(RcppArmadillo)
                                                             // It returns the number of columns of the input matrix
> # Source Rcpp functions from file
                                                             // It uses \emph{RcppArmadillo}.
> Rcpp::sourceCpp(file="/Users/jerzy/Develop/lecture_slides/scripts///, @export
> matv <- matrix(runif(1e5), nc=1e3)
                                                             // [[Rcpp::export]]
> # Center matrix columns using apply()
                                                             int demeanr(arma::mat& matv) {
> matd <- apply(matv, 2, function(x) (x-mean(x)))
                                                               for (uword i = 0; i < matv.n_cols; i++) {
> # Center matrix columns in place using Rcpp demeanr()
                                                                 matv.col(i) -= arma::mean(matv.col(i)):
> demeanr(matv)
                                                               } // end for
> all.equal(matd. matv)
                                                               return matv.n cols:
> # Microbenchmark \emph{RcppArmadillo} code
                                                             } // end demeanr
> library(microbenchmark)

                                                            svdval = svdval.subvec(0, dimax):
                                                            svdu = svdu.cols(0, dimax):
                                                            svdv = svdv.cols(0, dimax):
                                                            // Calculate the regularized inverse from the SVD deco
```

return svdv*arma::diagmat(1/svdval)*svdu.t();

+ rcpp = calc_inv(cormat, dimax=dimax),

+ times=100))[, c(1, 4, 5)] # end microbenchmark summary

Portfolio Optimization Using RcppArmadillo

Fast portfolio optimization using matrix algebra can be implemented using RcppArmadillo.

```
// Fast portfolio optimization using matrix algebra and \emph{RcppArmadillo}
arma::vec calc_weights(const arma::mat& returns, // Asset returns
                       Rcpp::List controlv) { // List of portfolio optimization parameters
 // Apply different calculation methods for weights
  switch(calc_method(method)) {
  case methodenum::maxsharpe: {
    // Mean returns of columns
    arma::vec colmeans = arma::trans(arma::mean(returns, 0));
    // Shrink colmeans to the mean of returns
    colmeans = ((1-alpha)*colmeans + alpha*arma::mean(colmeans));
    // Calculate weights using regularized inverse
    weights = calc inv(covmat, dimax, eigen thresh)*colmeans;
    break:
 } // end maxsharpe
 case methodenum::maxsharpemed: {
    // Median returns of columns
    arma::vec colmeans = arma::trans(arma::median(returns, 0));
    // Shrink colmeans to the median of returns
    colmeans = ((1-alpha)*colmeans + alpha*arma::median(colmeans));
    // Calculate weights using regularized inverse
    weights = calc inv(covmat. dimax. eigen thresh)*colmeans:
    break:
  } // end maxsharpemed
  case methodenum::minvarlin: {
    // Minimum variance weights under linear constraint
    // Multiply regularized inverse times unit vector
    weights = calc_inv(covmat, dimax, eigen_thresh)*arma::ones(ncols);
    break:
  } // end minvarlin
  case methodenum::minvarquad: {
    // Minimum variance weights under quadratic constraint
    // Calculate highest order principal component
    arma::vec eigenval;
    arma::mat eigenvec;
```

Strategy Backtesting Using RcppArmadillo

Fast backtesting of strategies can be implemented using RcppArmadillo.

```
arma::mat back_test(const arma::mat& excess, // Asset excess returns
                    const arma::mat& returns, // Asset returns
                    Rcpp::List controlv, // List of portfolio optimization model parameters
                    arma::uvec startp, // Start points
                    arma::uvec endd, // End points
                   double lambda = 0.0, // Decay factor for averaging the portfolio weights
                   double coeff = 1.0, // Multiplier of strategy returns
                   double bidask = 0.0) { // The bid-ask spread
 double lambda1 = 1-lambda;
 arma::uword nweights = returns.n_cols;
 arma::vec weights(nweights, fill::zeros);
 arma::vec weights past = ones(nweights)/stdev::sgrt(nweights):
 arma::mat pnls = zeros(returns.n rows. 1):
 // Perform loop over the end points
 for (arma::uword it = 1: it < endd.size(): it++) {
   // cout << "it: " << it << endl:
   // Calculate the portfolio weights
   weights = coeff*calc_weights(excess.rows(startp(it-1), endd(it-1)), controlv);
   // Calculate the weights as the weighted sum with past weights
   weights = lambda1*weights + lambda*weights past:
   // Calculate out-of-sample returns
   pnls.rows(endd(it-1)+1, endd(it)) = returns.rows(endd(it-1)+1, endd(it))*weights:
   // Add transaction costs
   pnls.row(endd(it-1)+1) -= bidask*sum(abs(weightv - weights_past))/2;
   // Copy the weights
   weights past = weights:
 } // end for
 // Return the strategy pnls
 return pnls;
} // end back_test
```

Package reticulate for Running Python from RStudio

The package *reticulate* allows running Python functions and scripts from RStudio.

> # Install package reticulate > install.packages("reticulate")

The package *reticulate* relies on Python for interpreting the Python code.

> # Start Python session
> reticulate::repl_python()

You must set your Global Options in RStudio to your

> # Exit Python session > exit

Python executable, for example: /Library/Frameworks/Python.framework/Versions/3.10/bin/python3.10

You can learn more about the package reticulate here:

https://rstudio.github.io/reticulate/

Running Python Under reticulate

```
....
Script for loading OHLC data from a CSV file and plotting a candlestick plot.
# Import packages
import pandas as pd
import numpy as np
import plotly.graph_objects as go
# Load OHLC data from csv file - the time index is formatted inside read_csv()
symbol = "SPY"
range = "day"
filename = "/Users/jerzy/Develop/data/" + symbol + "_" + range + ".csv"
ohlc = pd.read_csv(filename)
datev = ohlc.Date
# Calculate log stock prices
ohlc[["Open", "High", "Low", "Close"]] = np.log(ohlc[["Open", "High", "Low", "Close"]])
# Calculate moving average
lookback = 55
closep = ohlc.Close
pricema = closep.ewm(span=lookback, adjust=False).mean()
# Plotly simple candlestick with moving average
# Create empty graph object
plotfig = go.Figure()
# Add trace for candlesticks
plotfig = plotfig.add_trace(go.Candlestick(x=datev,
 open=ohlc.Open, high=ohlc.High, low=ohlc.Low, close=ohlc.Close,
 name=symbol+" Log OHLC Prices", showlegend=False))
# Add trace for moving average
plotfig = plotfig.add_trace(go.Scatter(x=datev, y=pricema,
 name="Moving Average", line=dict(color="blue")))
# Customize plot
plotfig = plotfig.update lavout(title=symbol + " Log OHLC Prices".
  title font size=24. title font color="blue". vaxis title="Price".
 font color="black", font size=18, xaxis rangeslider visible=False)
# Customize legend
plotfig = plotfig.update lavout(legend=dict(x=0.2, v=0.9, traceorder="normal",
  itemsizing="constant", font=dict(family="sans-serif", size=18, color="blue")))
# Render the plot
```

plotfig.show()
